Joint work with Aviv Zohar and Laurent Vanbever

Routing attacks quite often make the news

# Russian-controlled telecom hijacks financial services' Internet traffic

Visa, MasterCard, and Symantec among dozens affected by "suspicious" BGP mishap.

DAN GOODIN - 4/27/2017, 10:20 PM

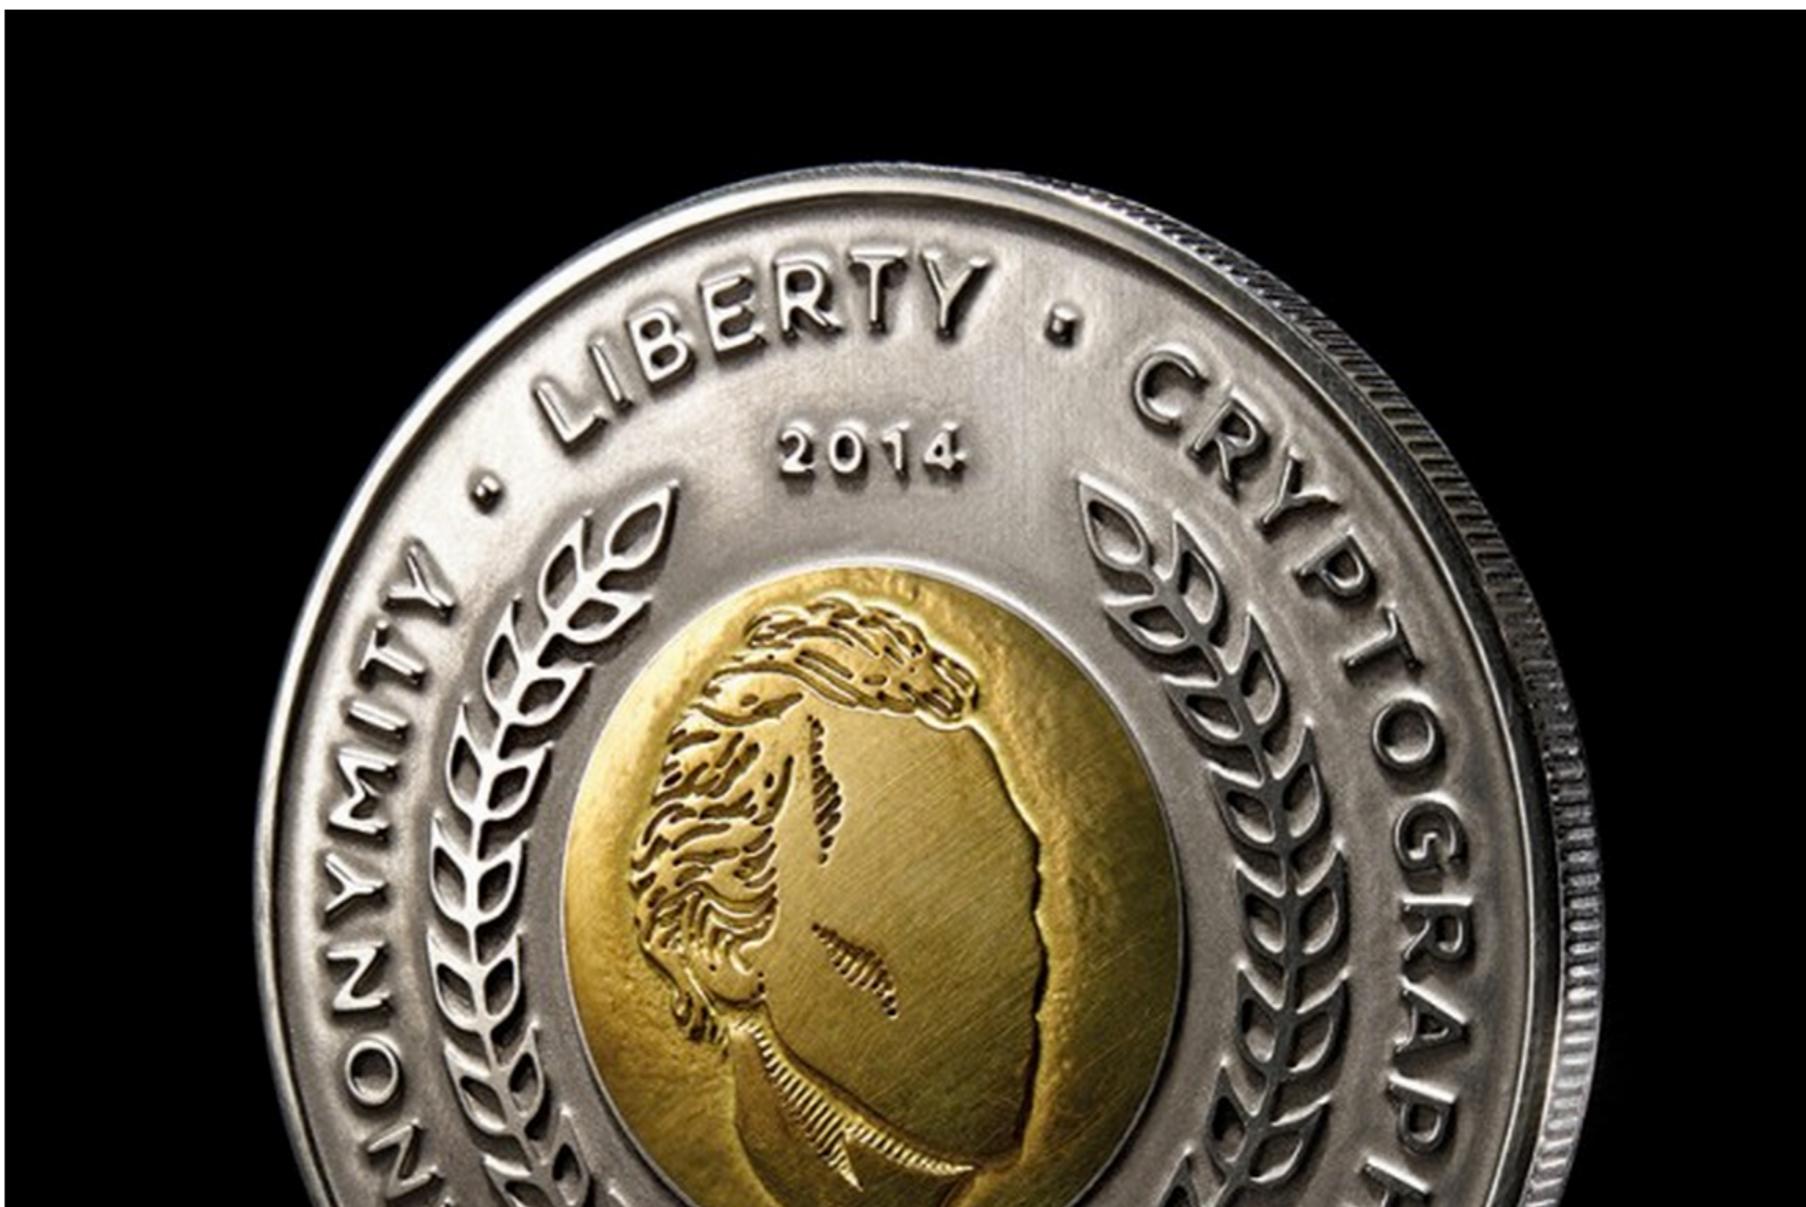

source: arstechnica.com

# Hacker Redirects Traffic From 19 Internet Providers to Steal Bitcoins

BY ANDY GREENBERG 08.07.14 | 1:00 PM | PERMALINK

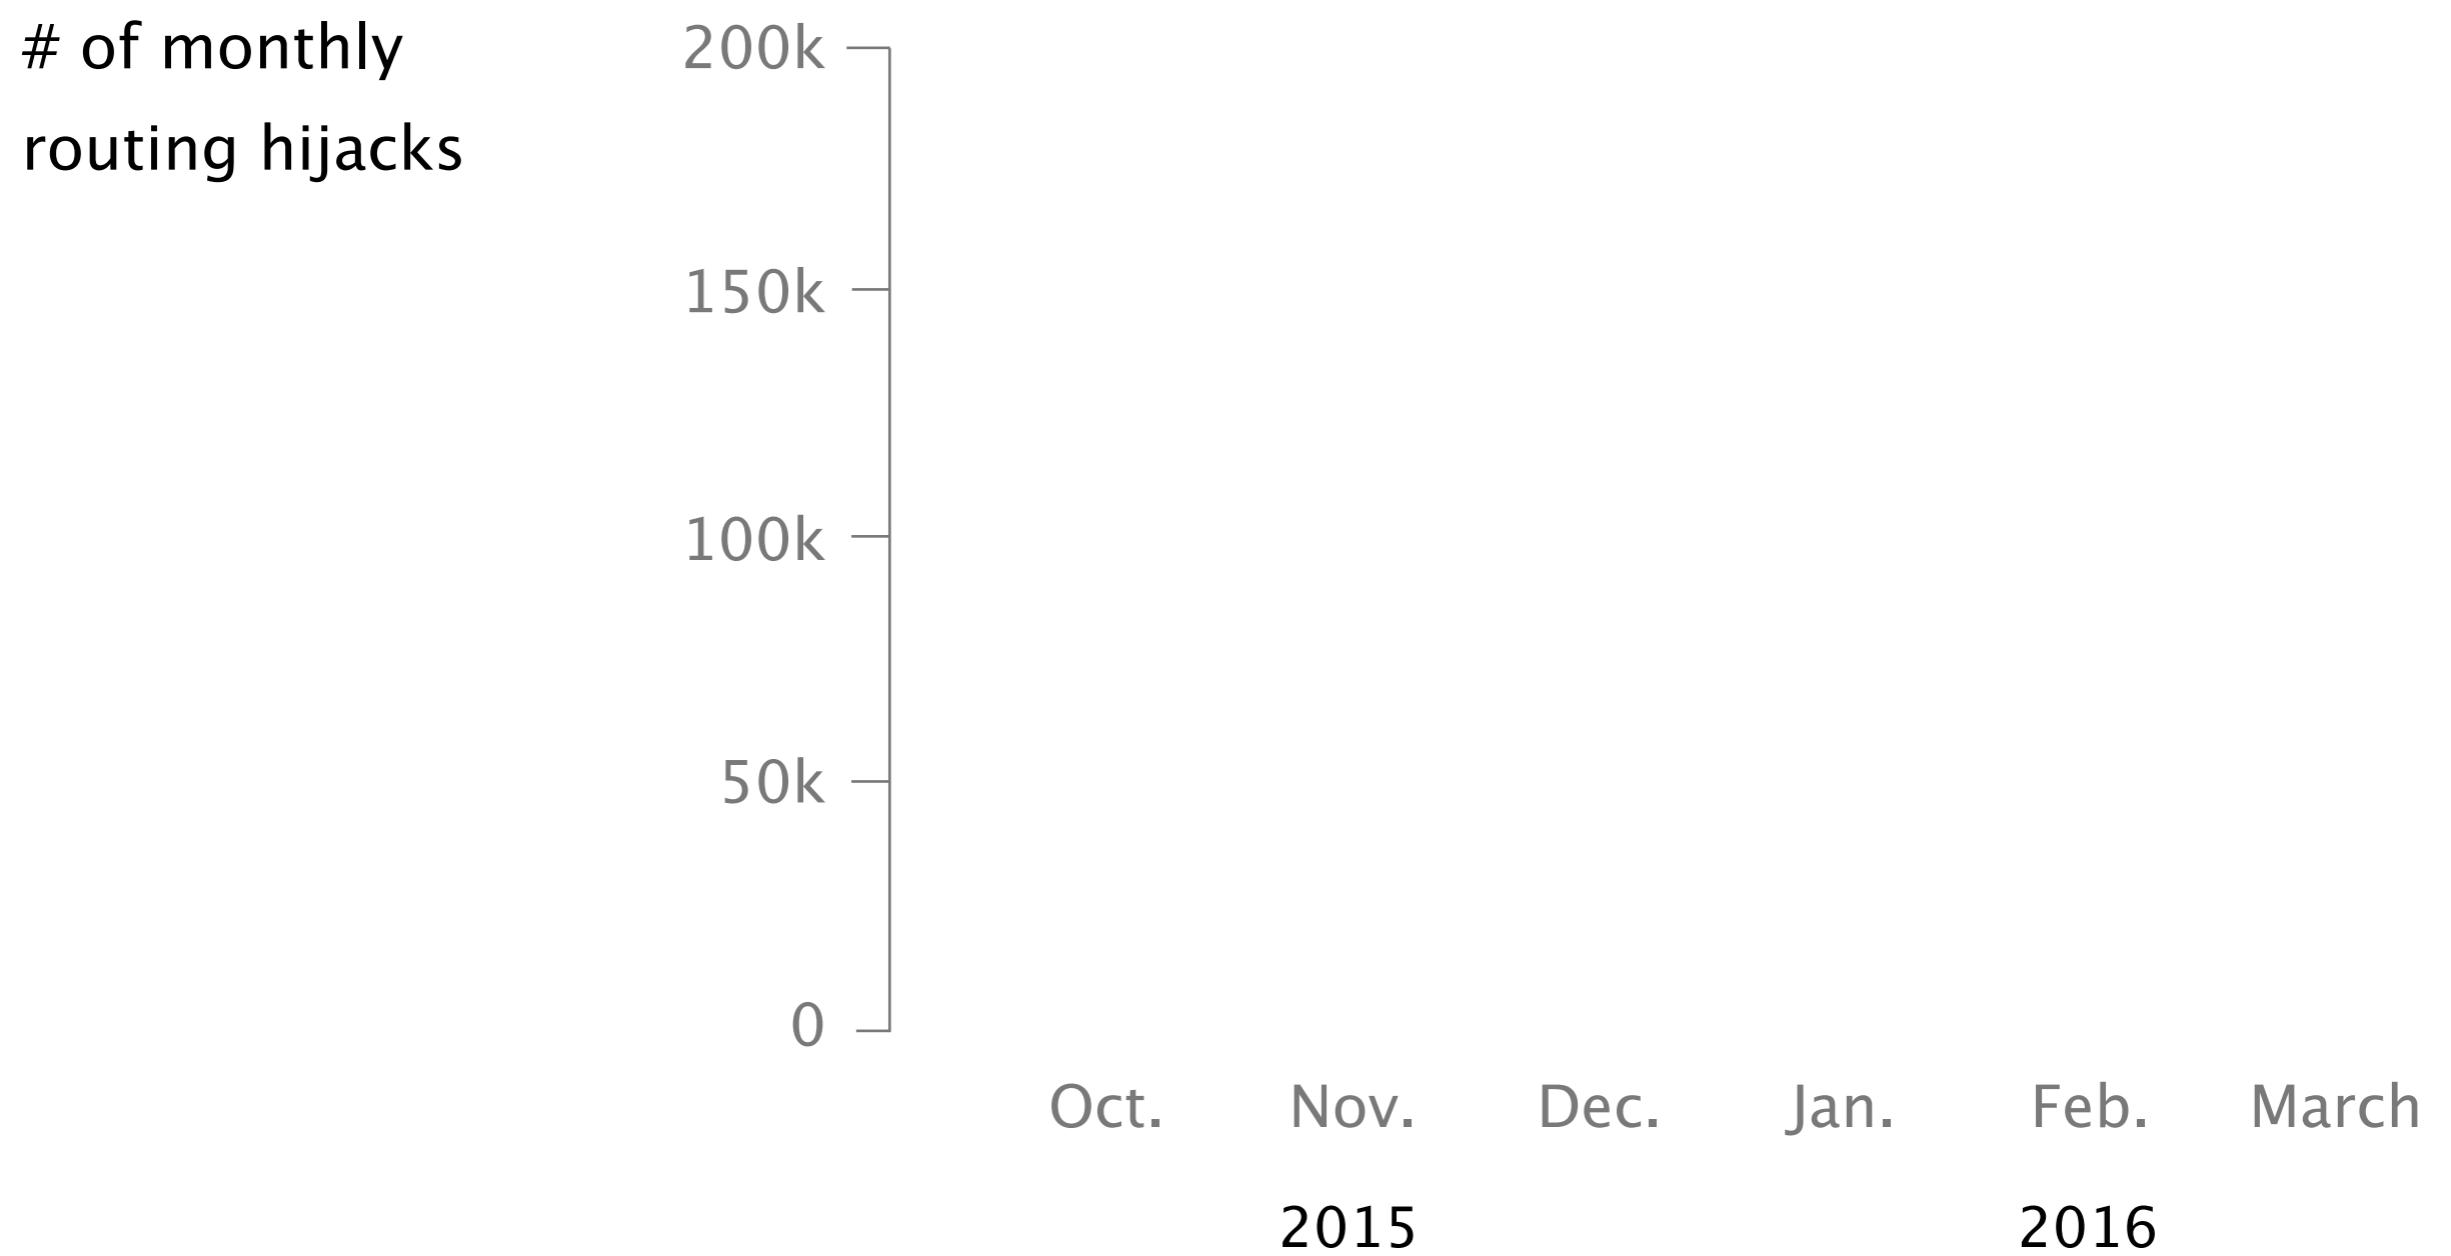

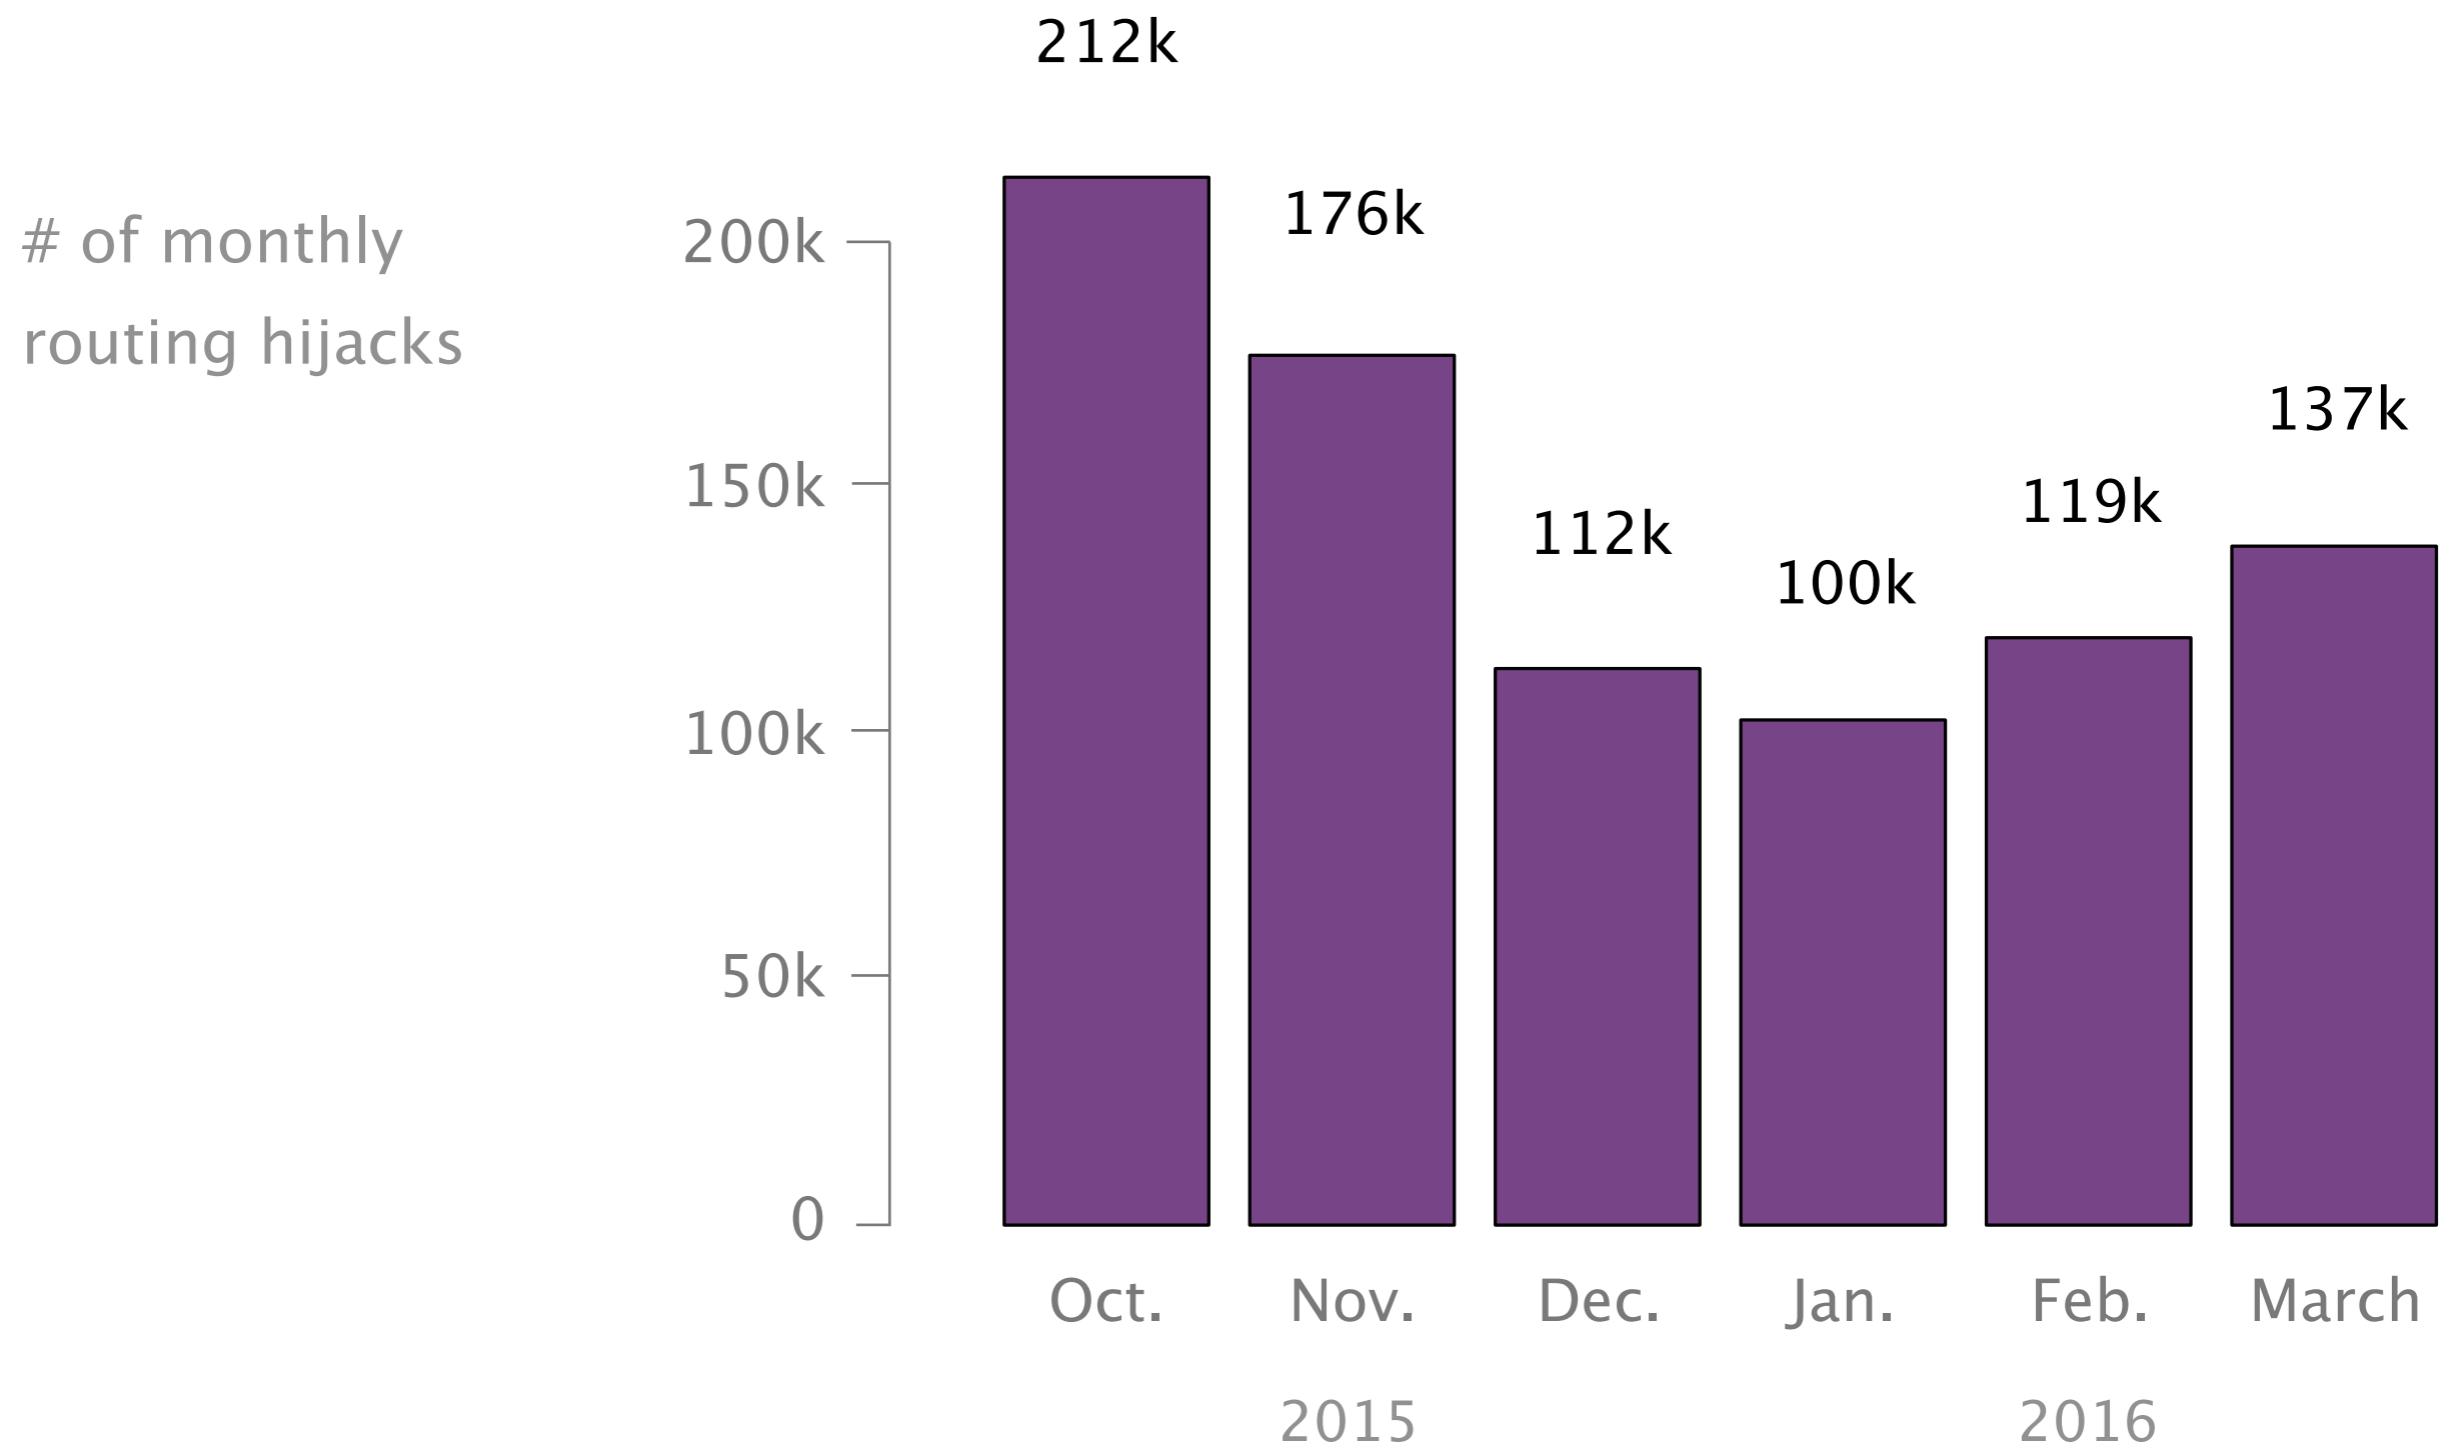

source: wired.com

That is only the **tip** of the **iceberg** of routing manipulations

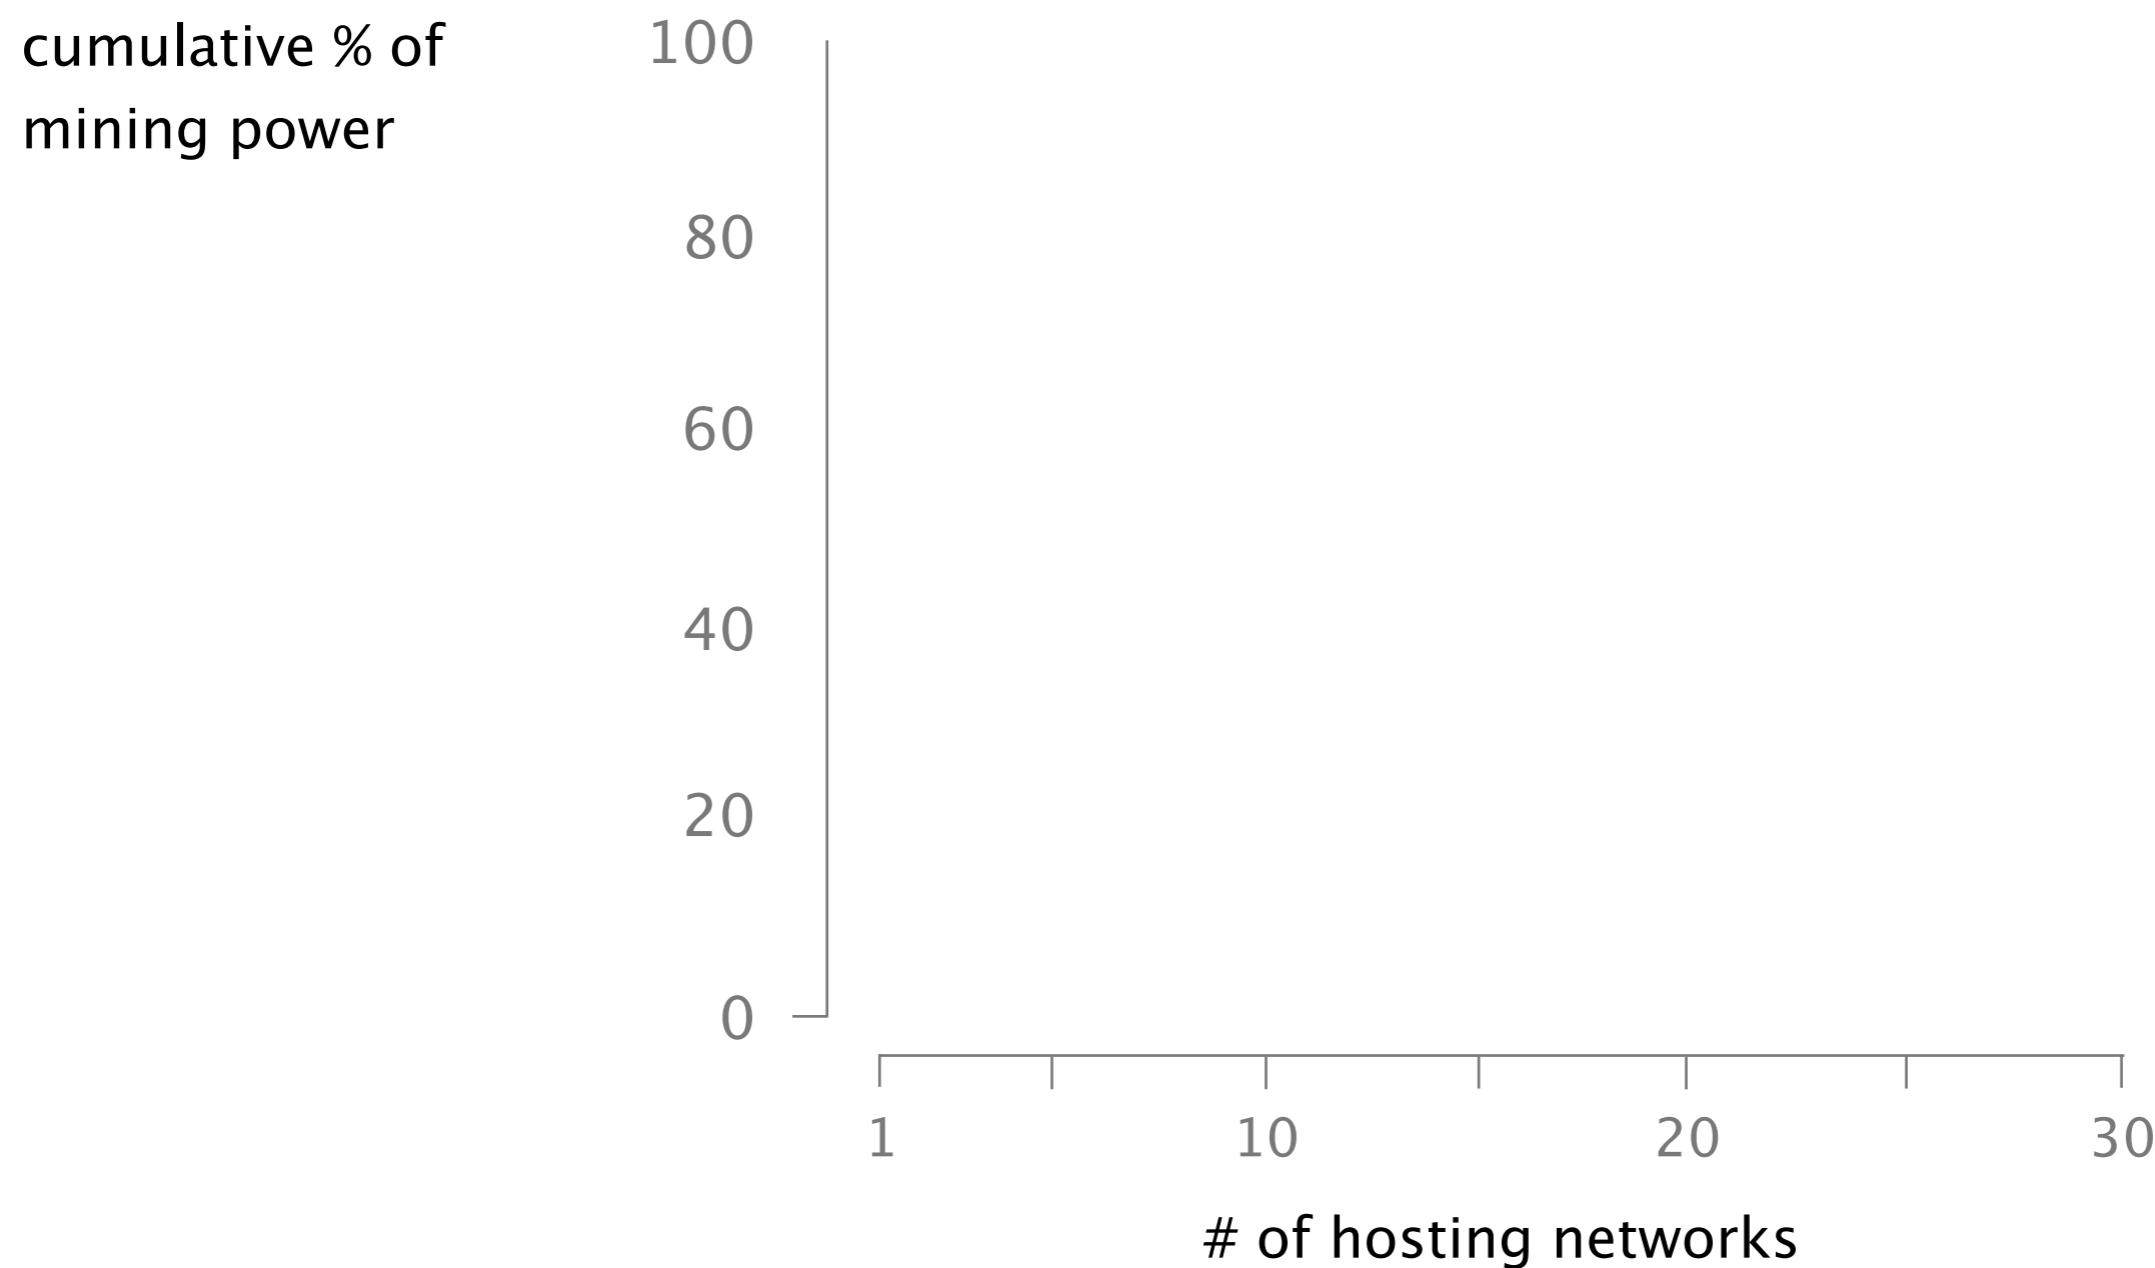

Can routing attacks impact Bitcoin?

Bitcoin is **highly decentralized**  
making it robust to routing attacks, **in theory...**

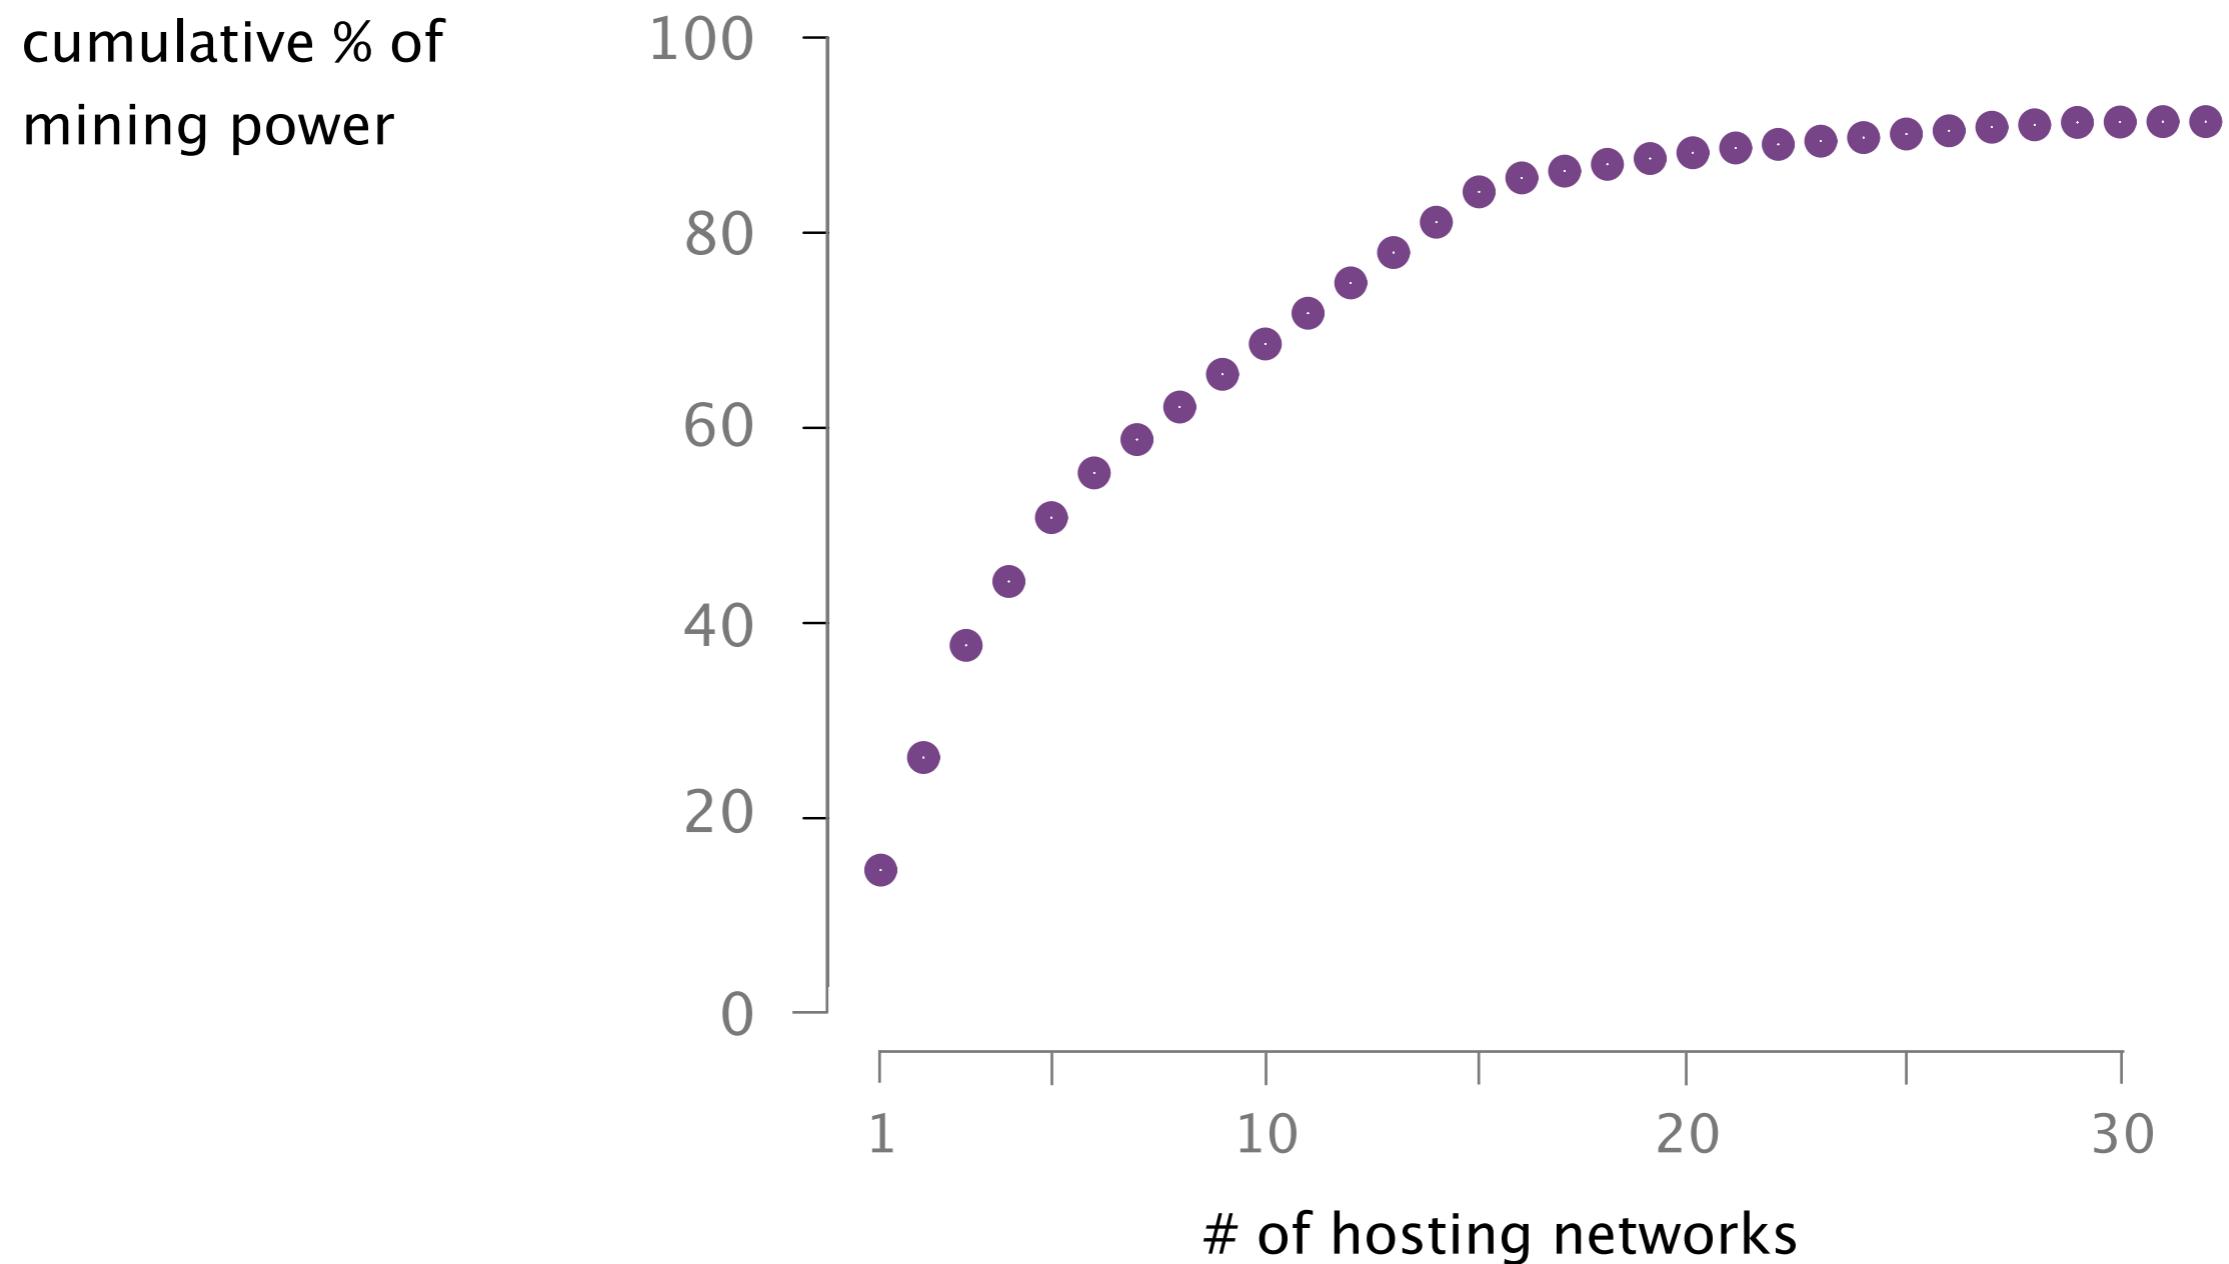

Bitcoin nodes ...

- are scattered all around the globe
- establish random connections
- use multihoming and extra relay networks

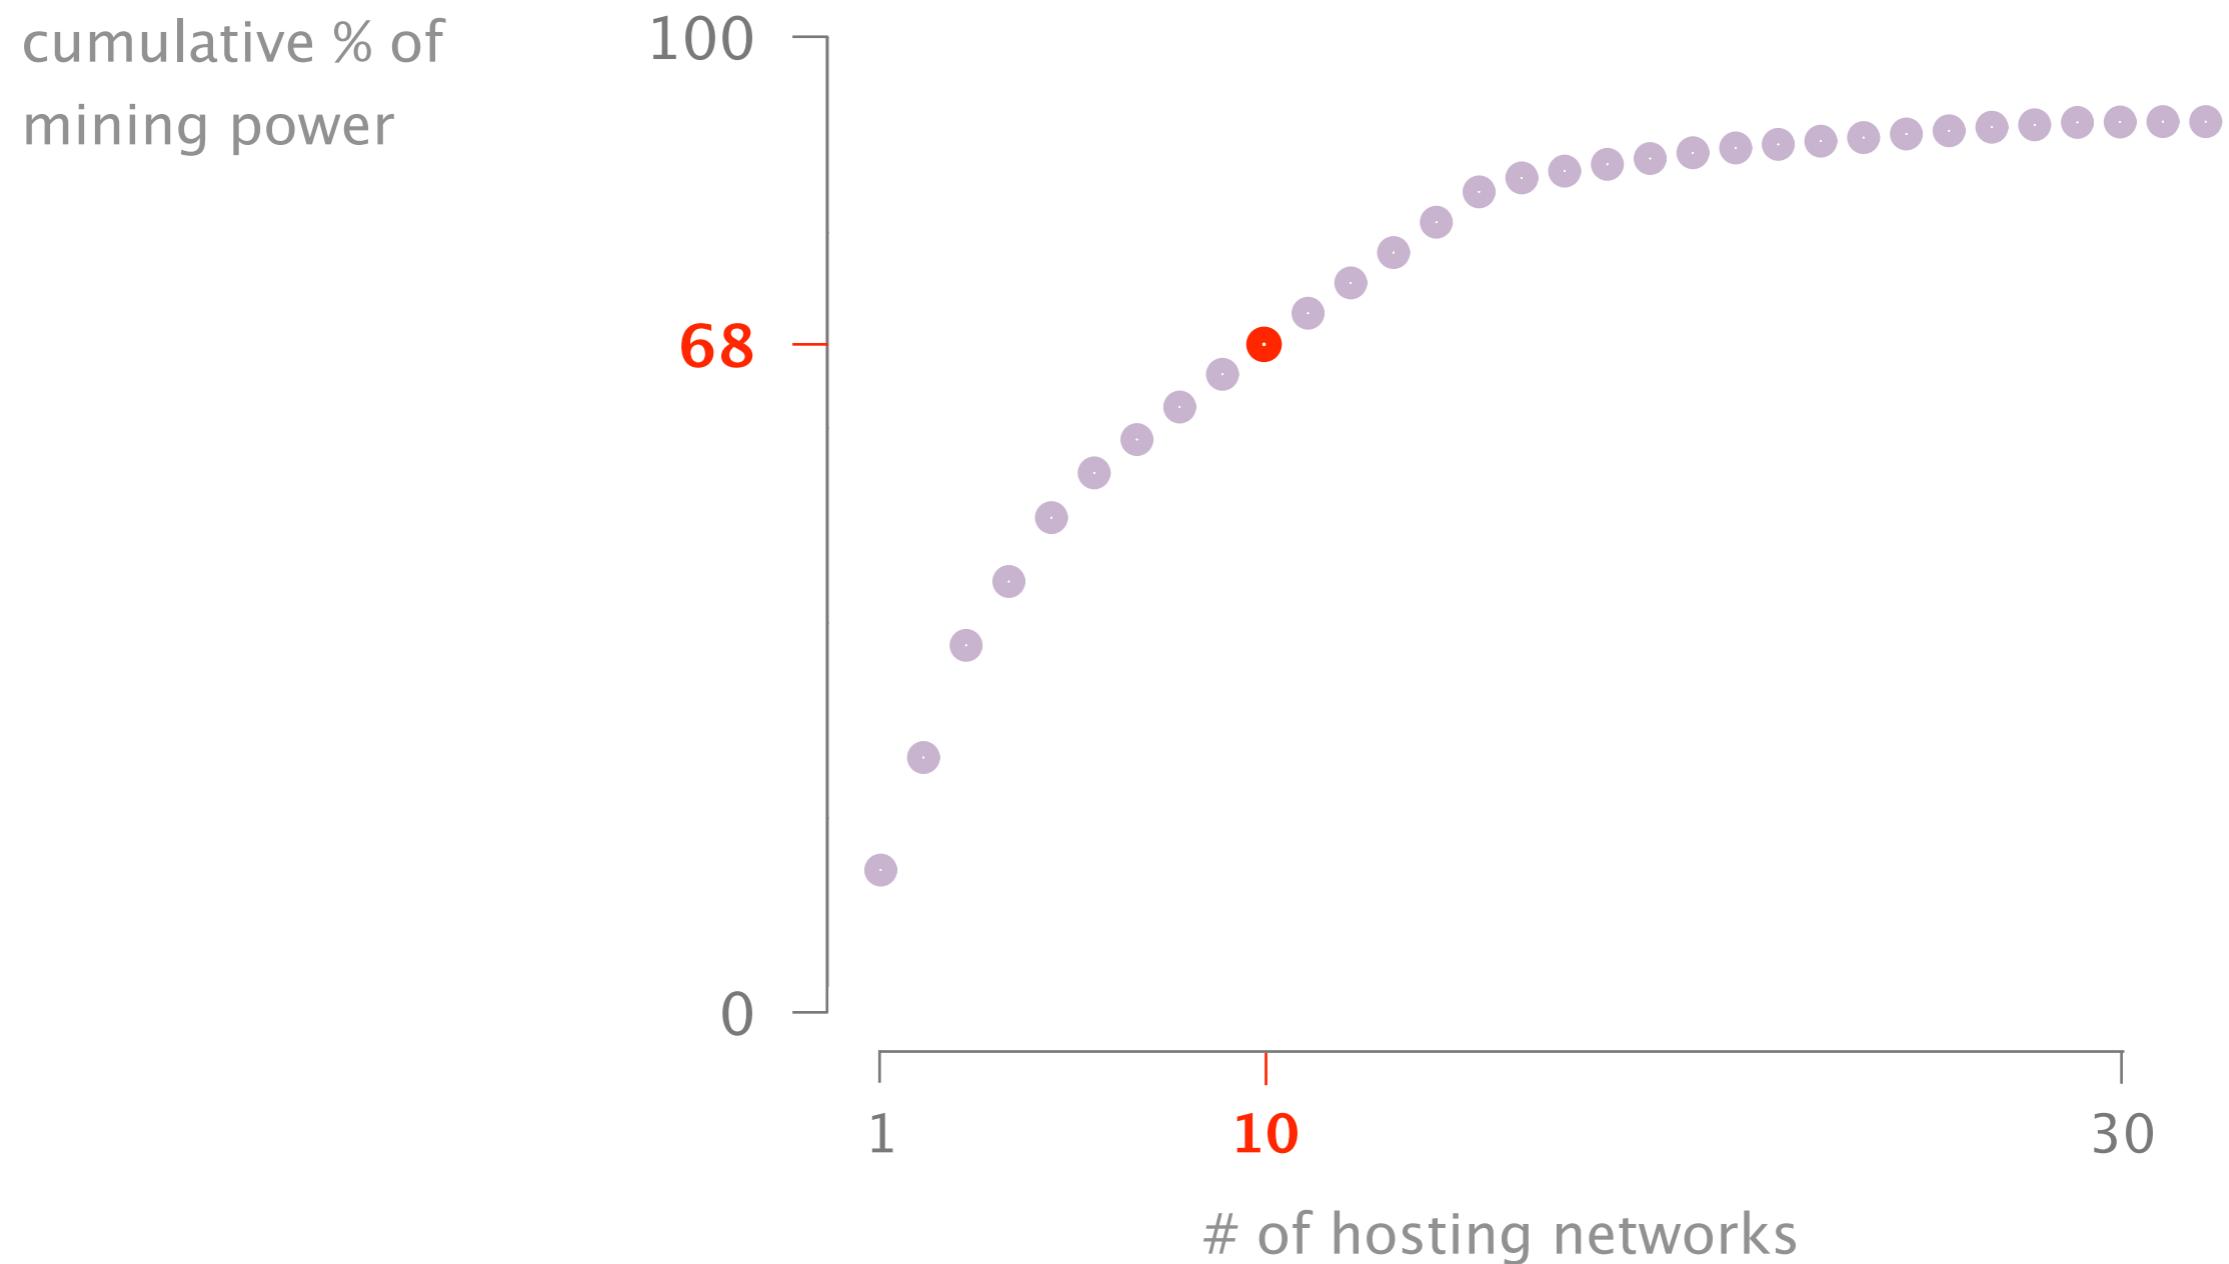

In practice, Bitcoin is **highly centralized**,  
both from a routing and mining viewpoint

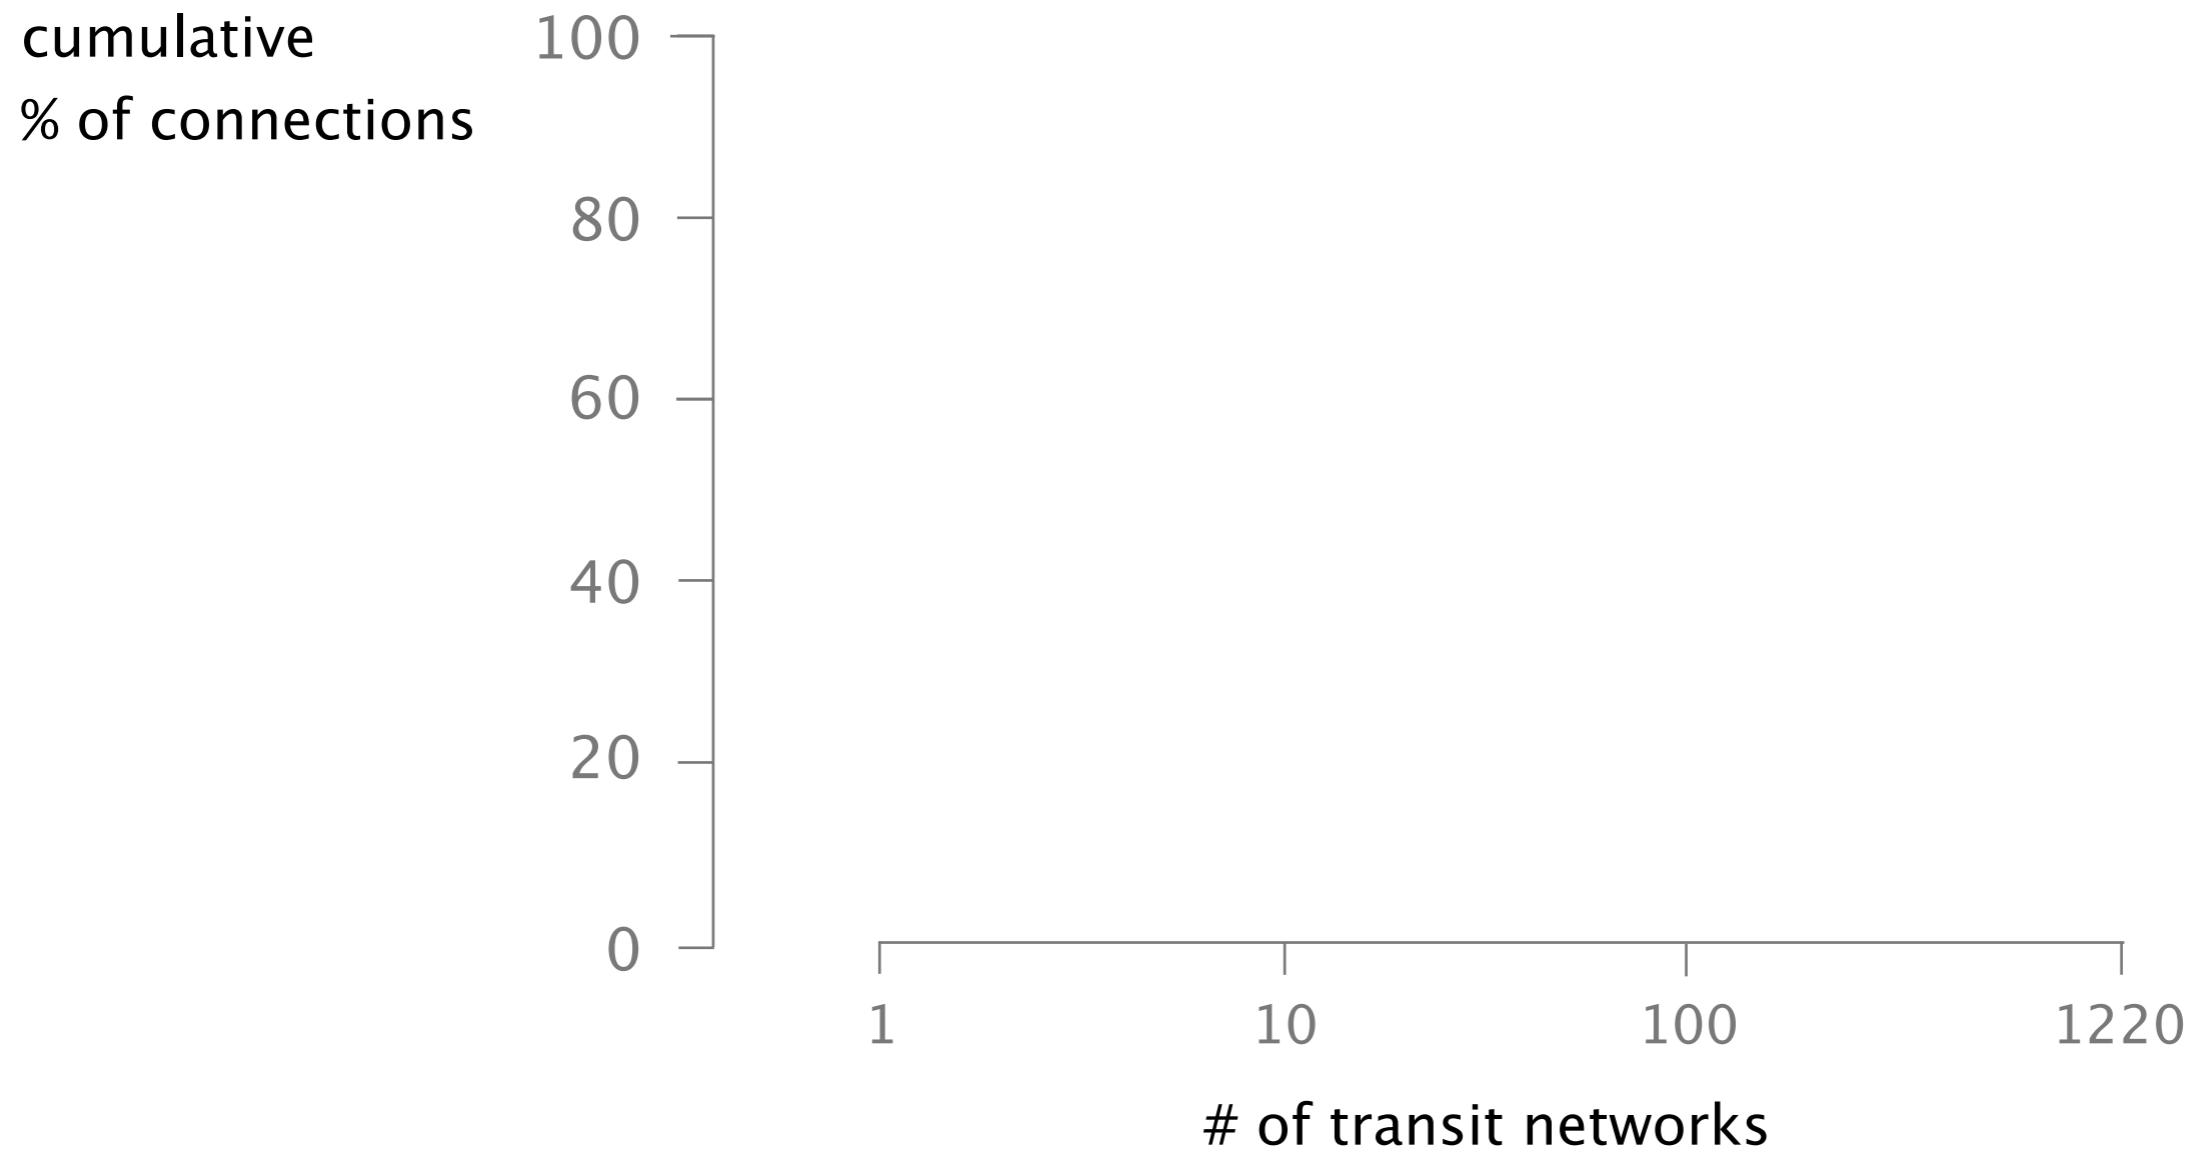

# Mining power is centralized to few hosting networks

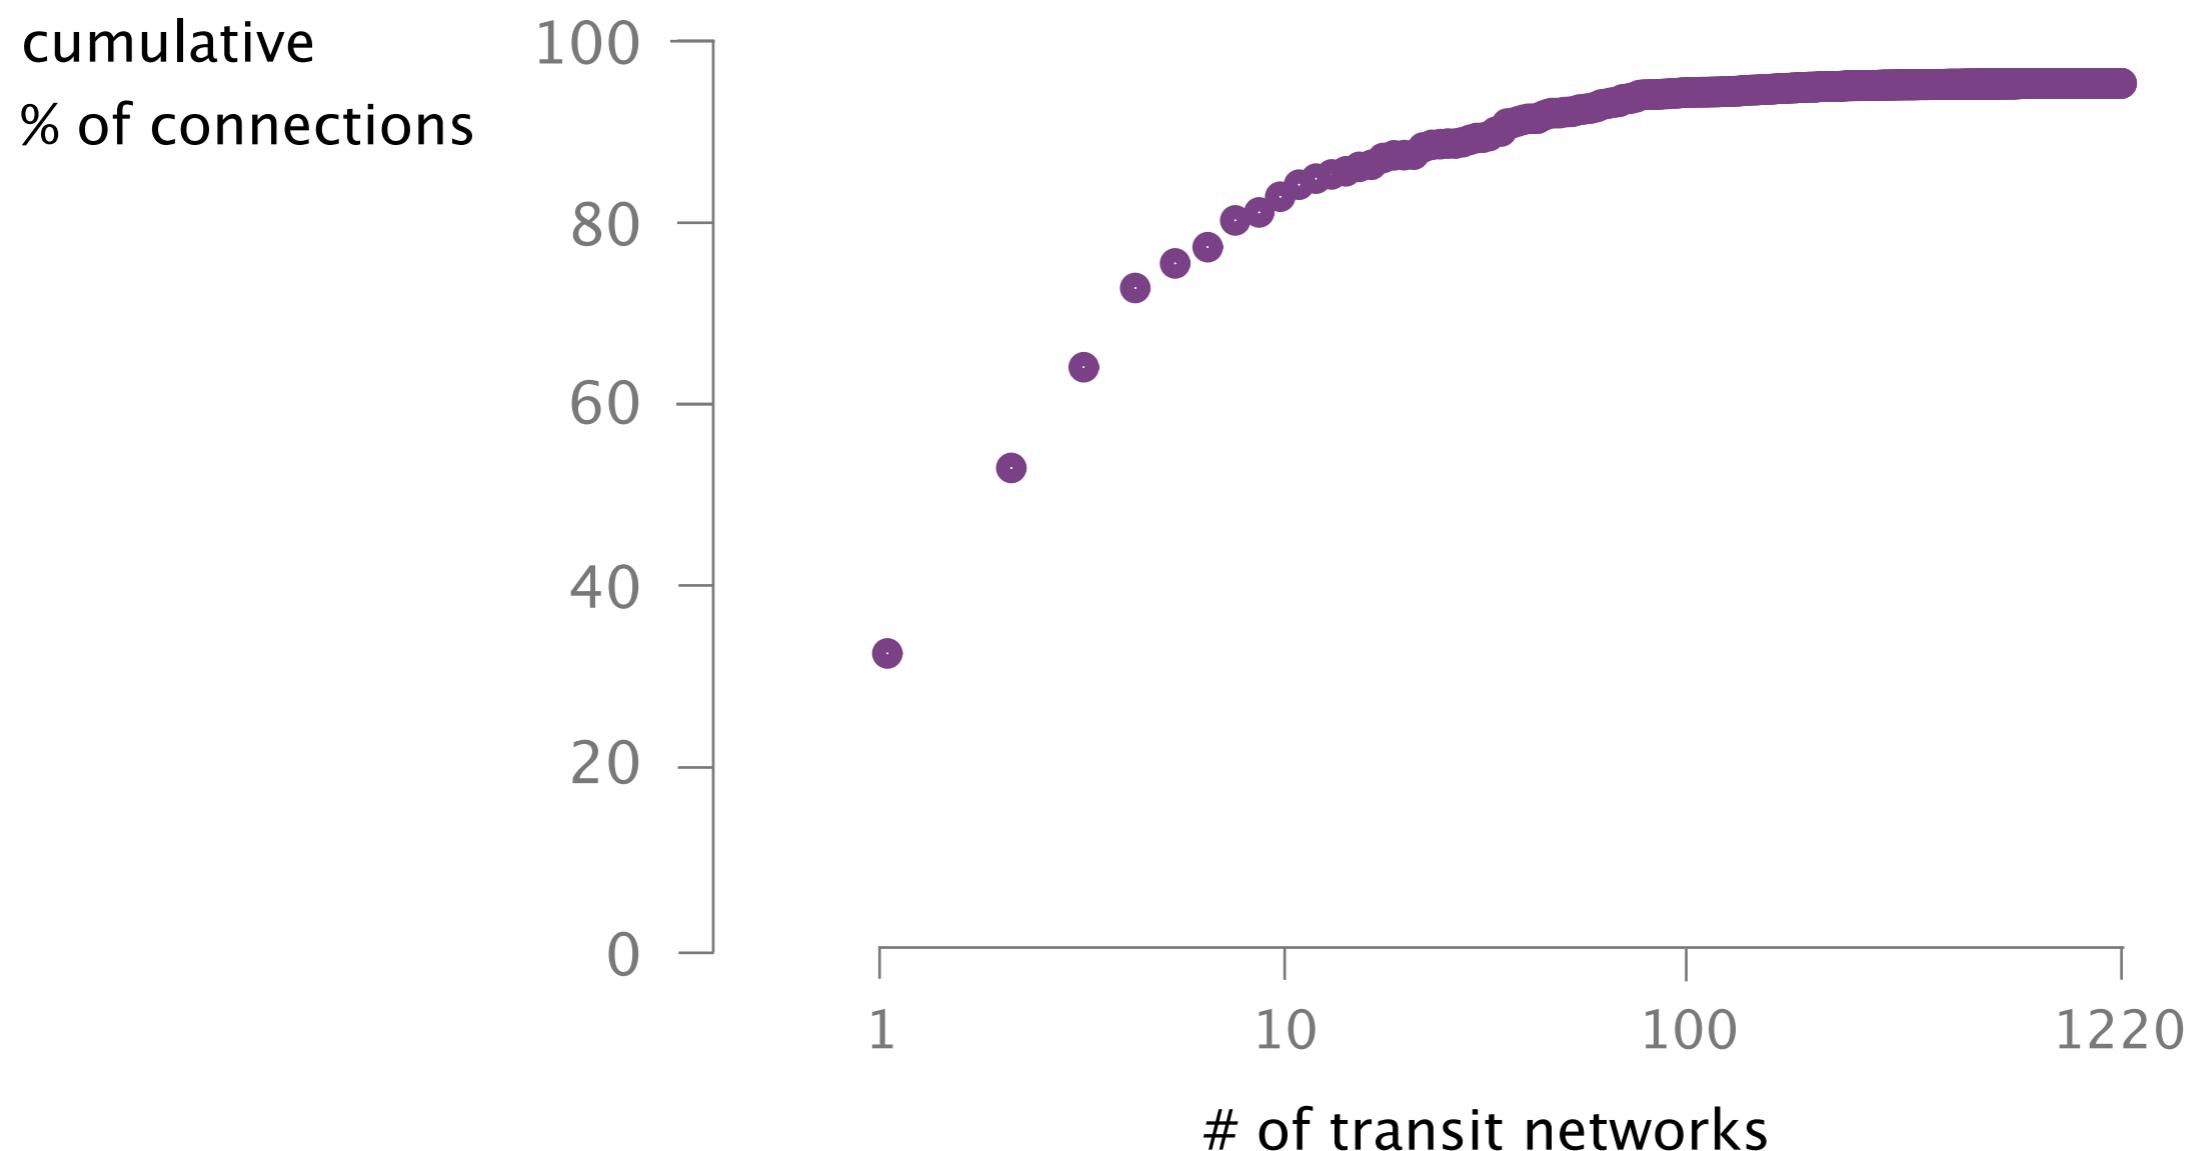

68% of the mining power is hosted in 10 networks only

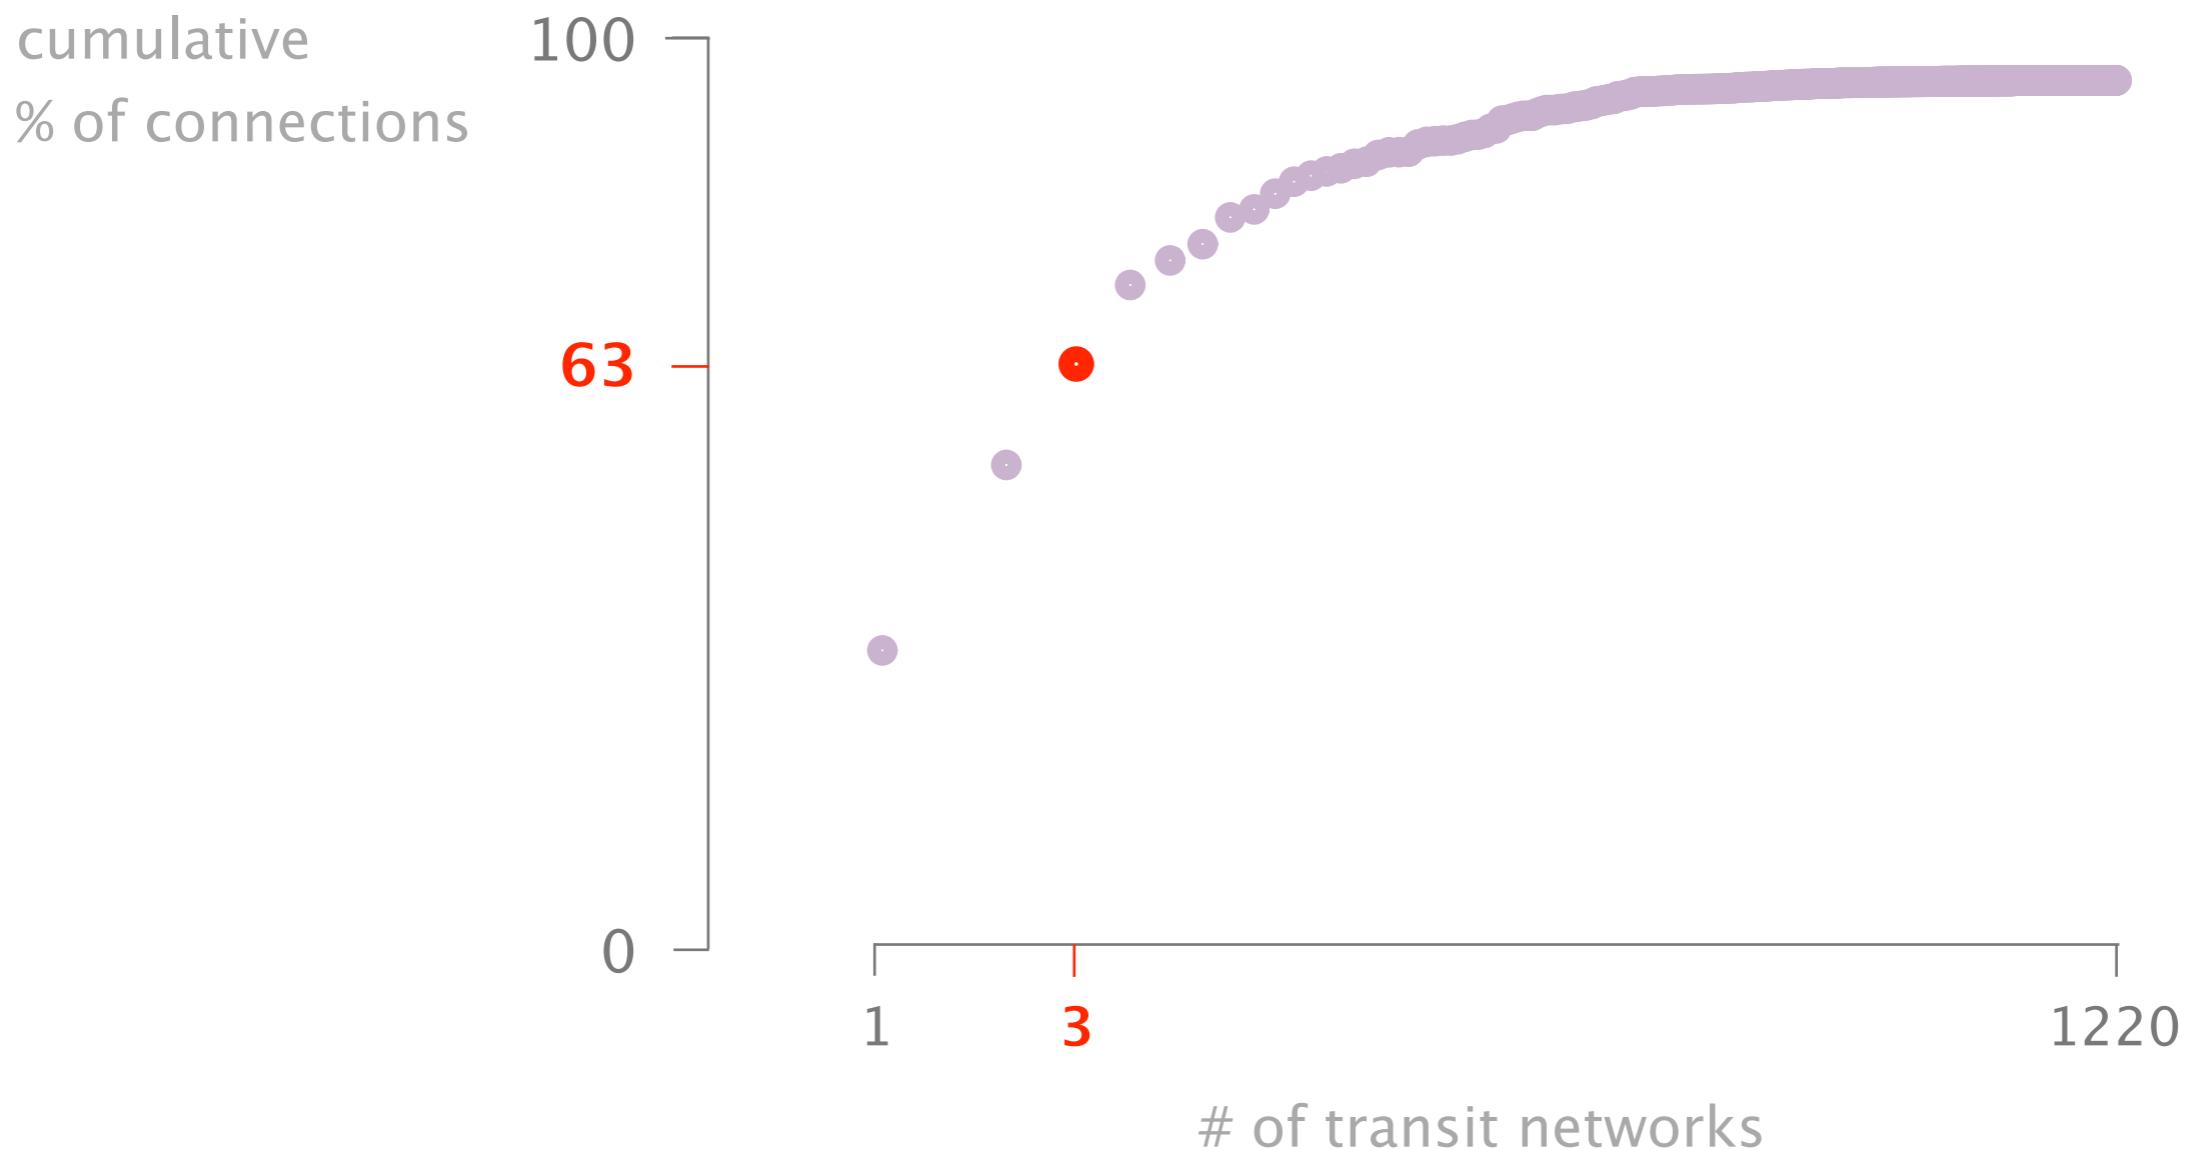

Likewise, a few transit networks can intercept a large fraction of the Bitcoin connections

3 transit networks see more than 60% of all connections

Because of these characteristics two routing attacks practical and effective today

Attack 1

Split the network in half

Attack 2

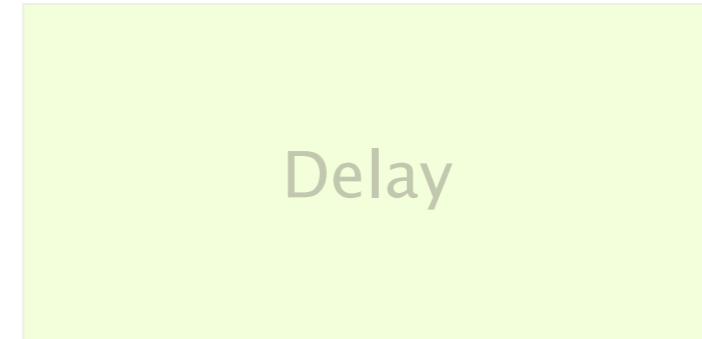

Delay block propagation

Each attack differs in terms of its visibility, impact, and targets

Attack 1

Attack 2

Partitioning

Delay

visible

network-wide attack

invisible

targeted attack (set of nodes)

Each attack differs in terms of its visibility, impact, and targets

Attack 1

visible

network-wide attack

Attack 2

invisible

targeted attack (set of nodes)

### **Background**

#### **BGP & Bitcoin**

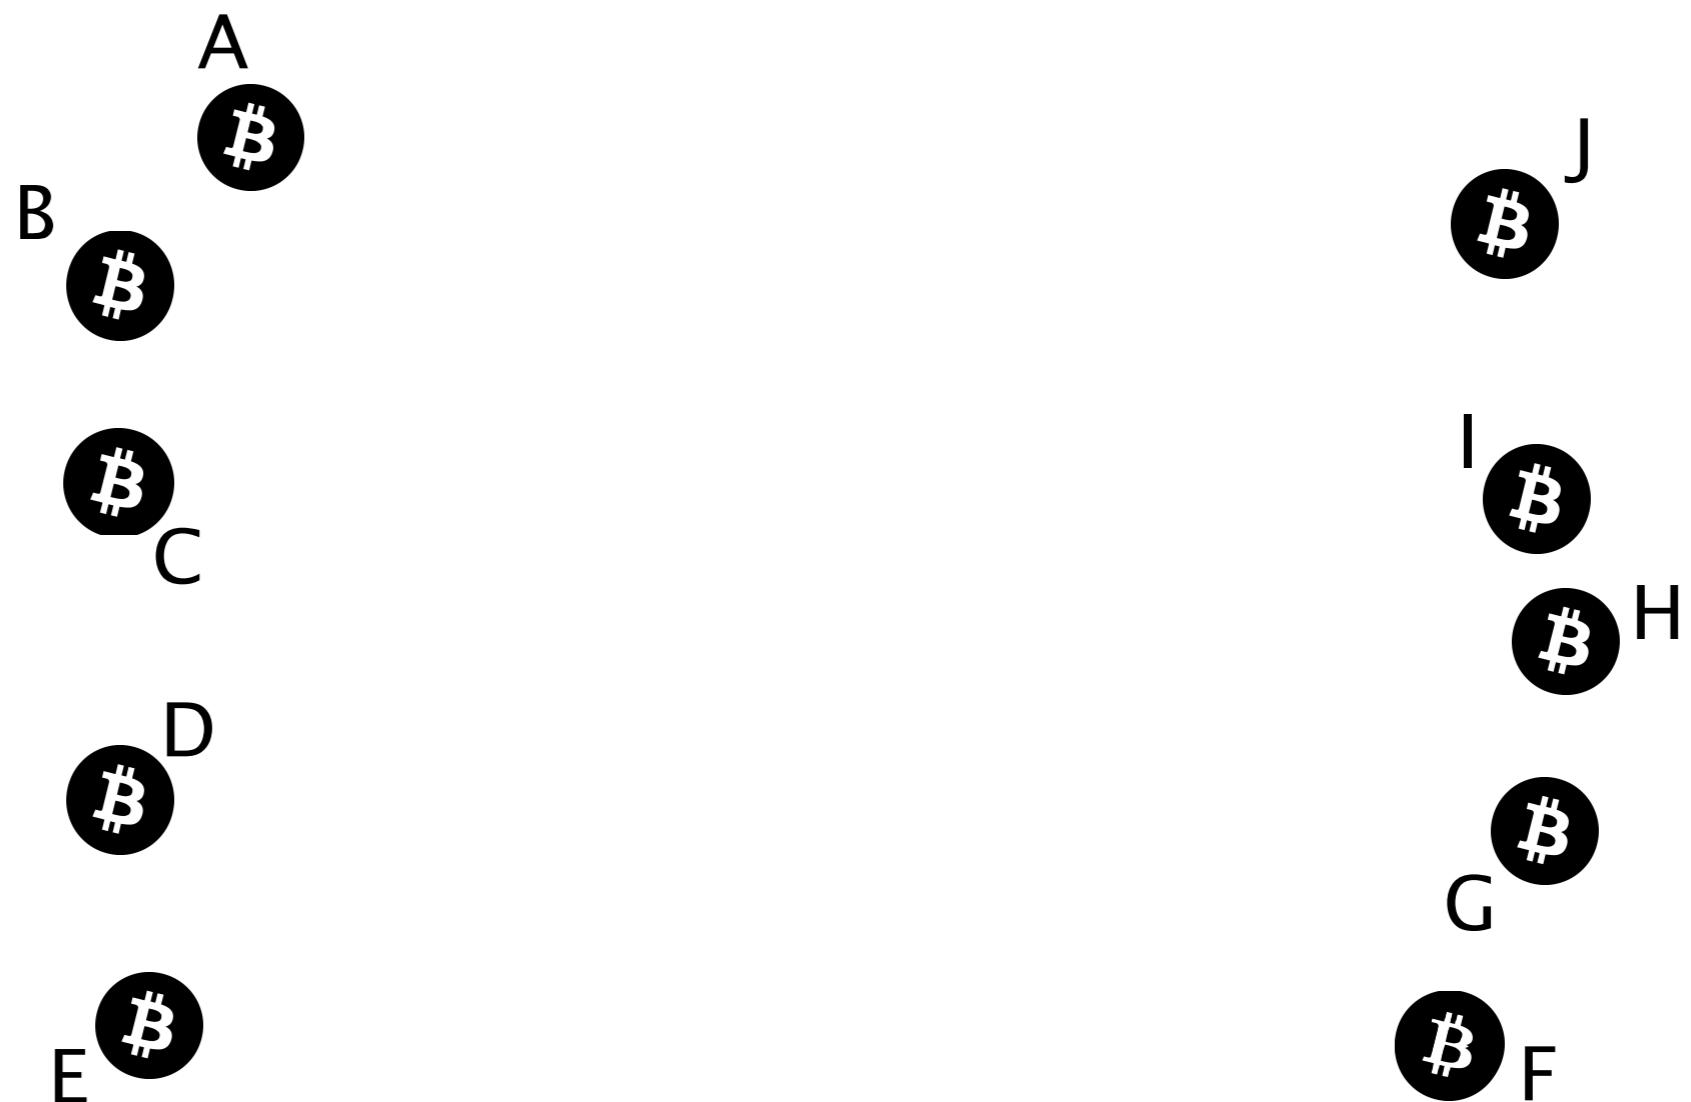

**Partitioning attack**  
splitting the network

**Delay attack**  
slowing the network down

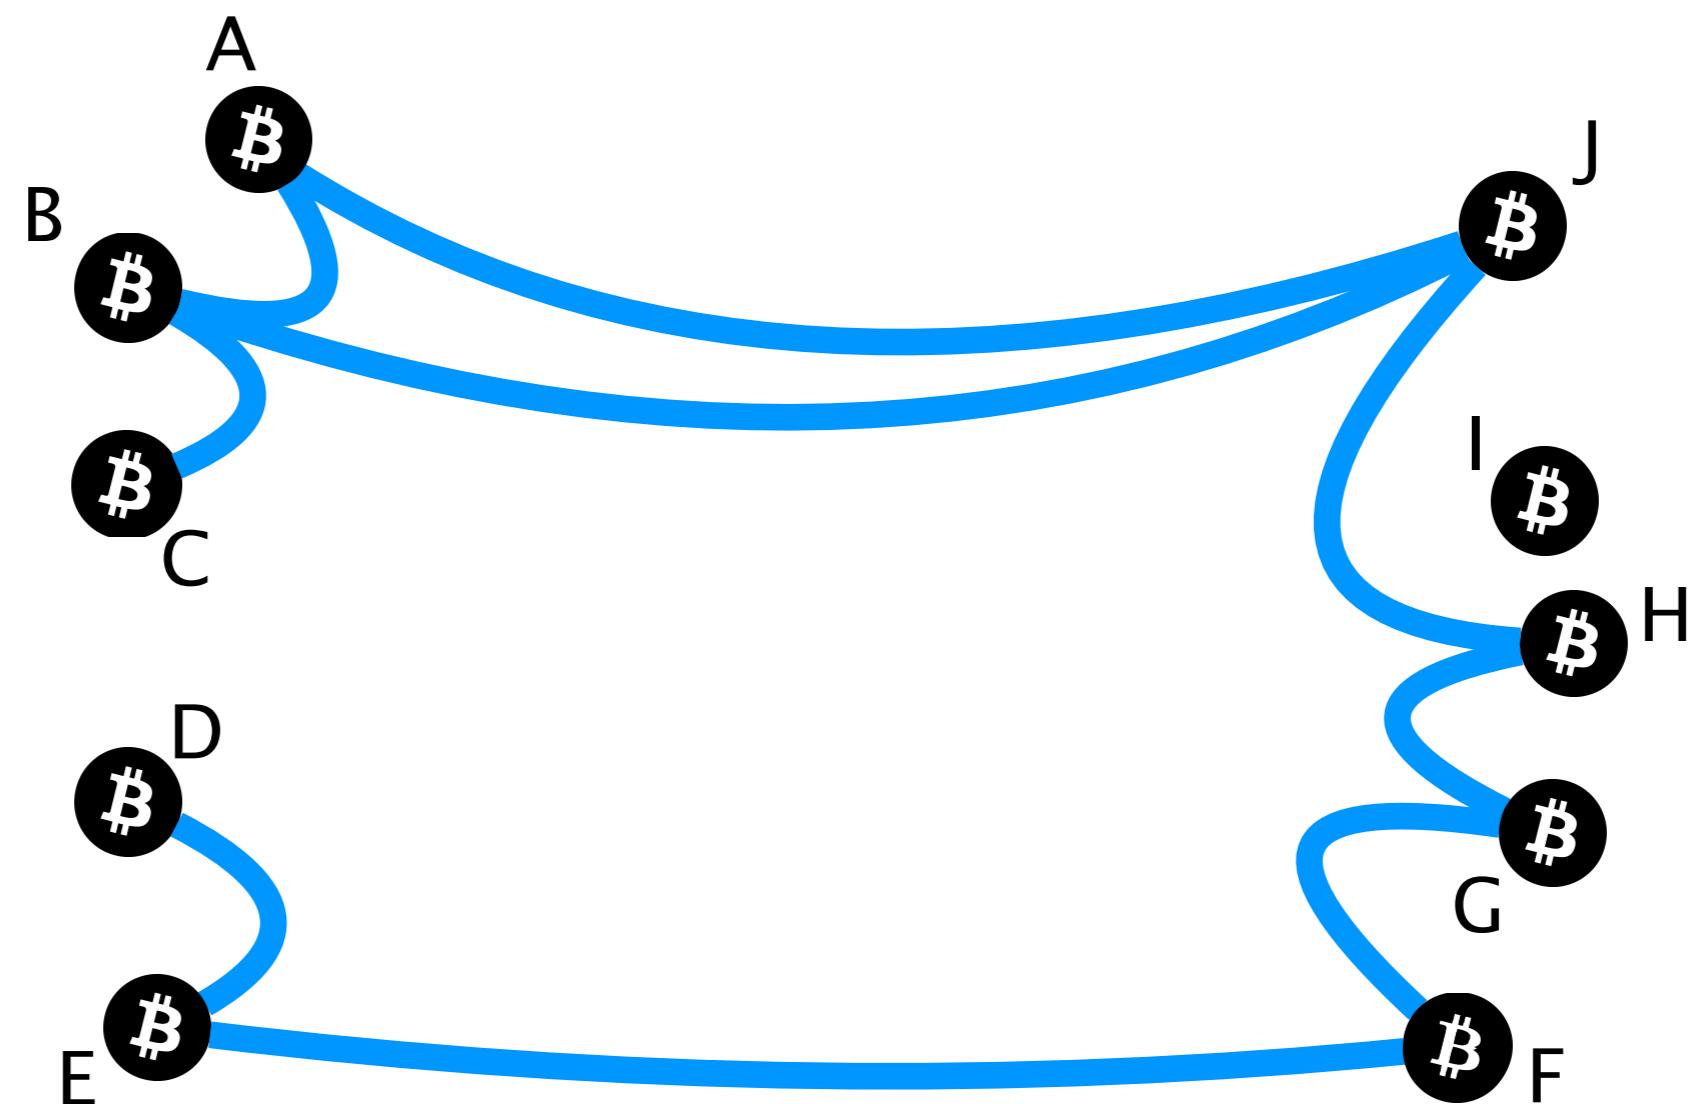

### **Countermeasures**

short-term & long-term

Bitcoin is a **distributed** network of nodes

Bitcoin nodes establish **random connections** between each other

Each node keeps a ledger of all **transactions** ever performed: “**the blockchain**”

Tx a1a53743

Tx x5f78432

Tx x5f78432

Tx b5x89433

Tx h1t91267

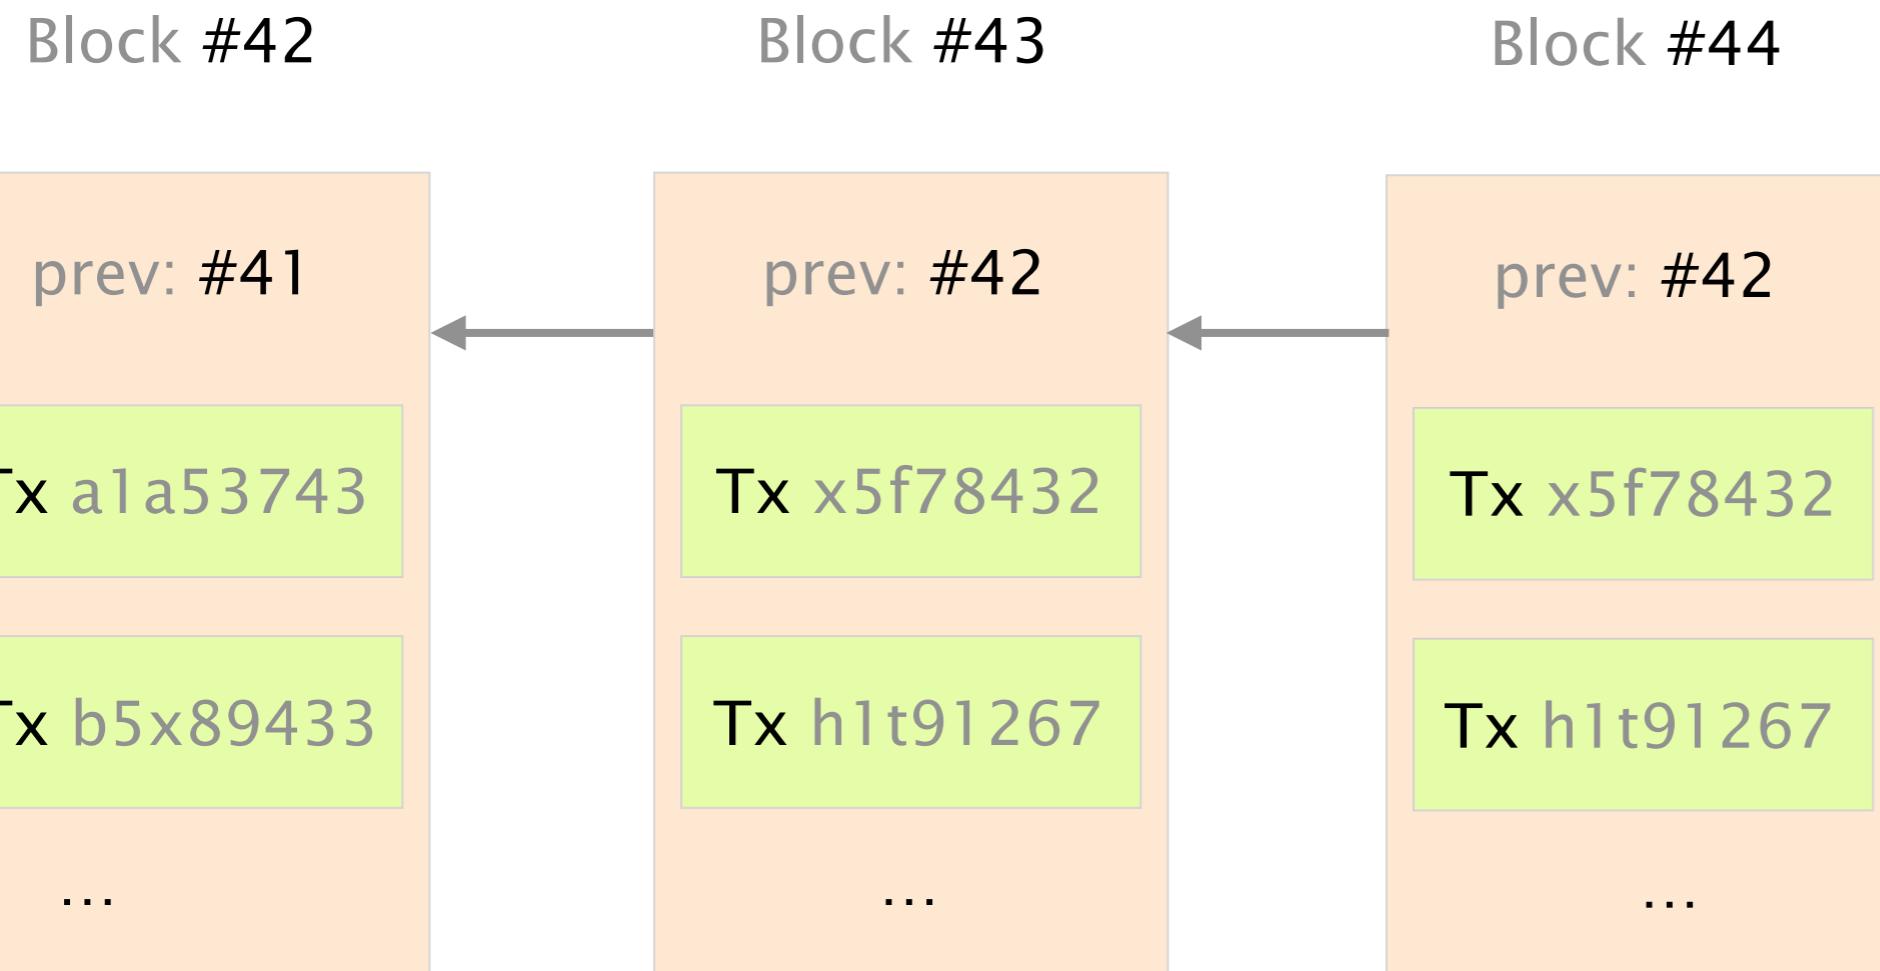

Tx h1t91267

...

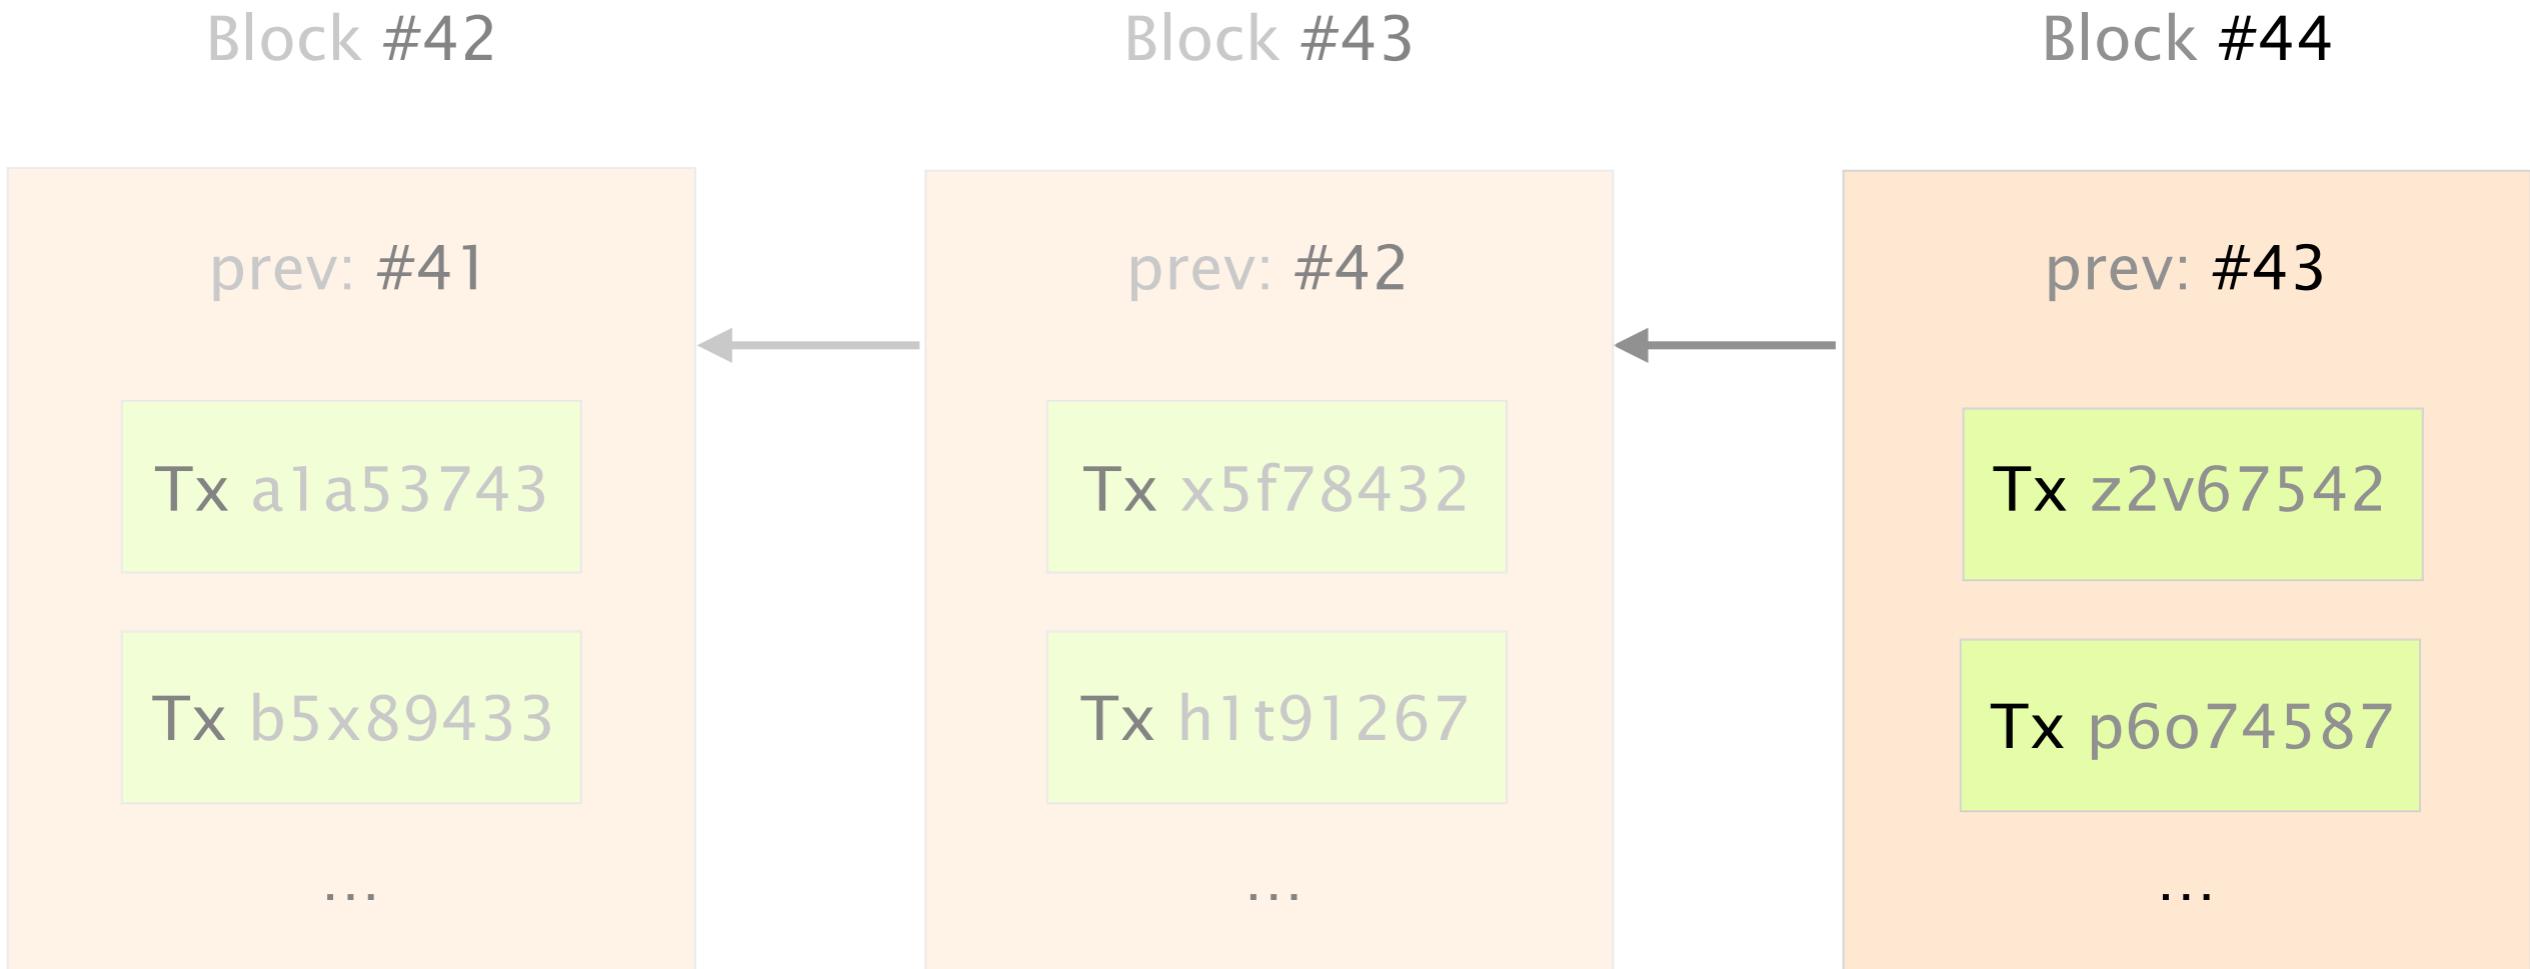

...

...

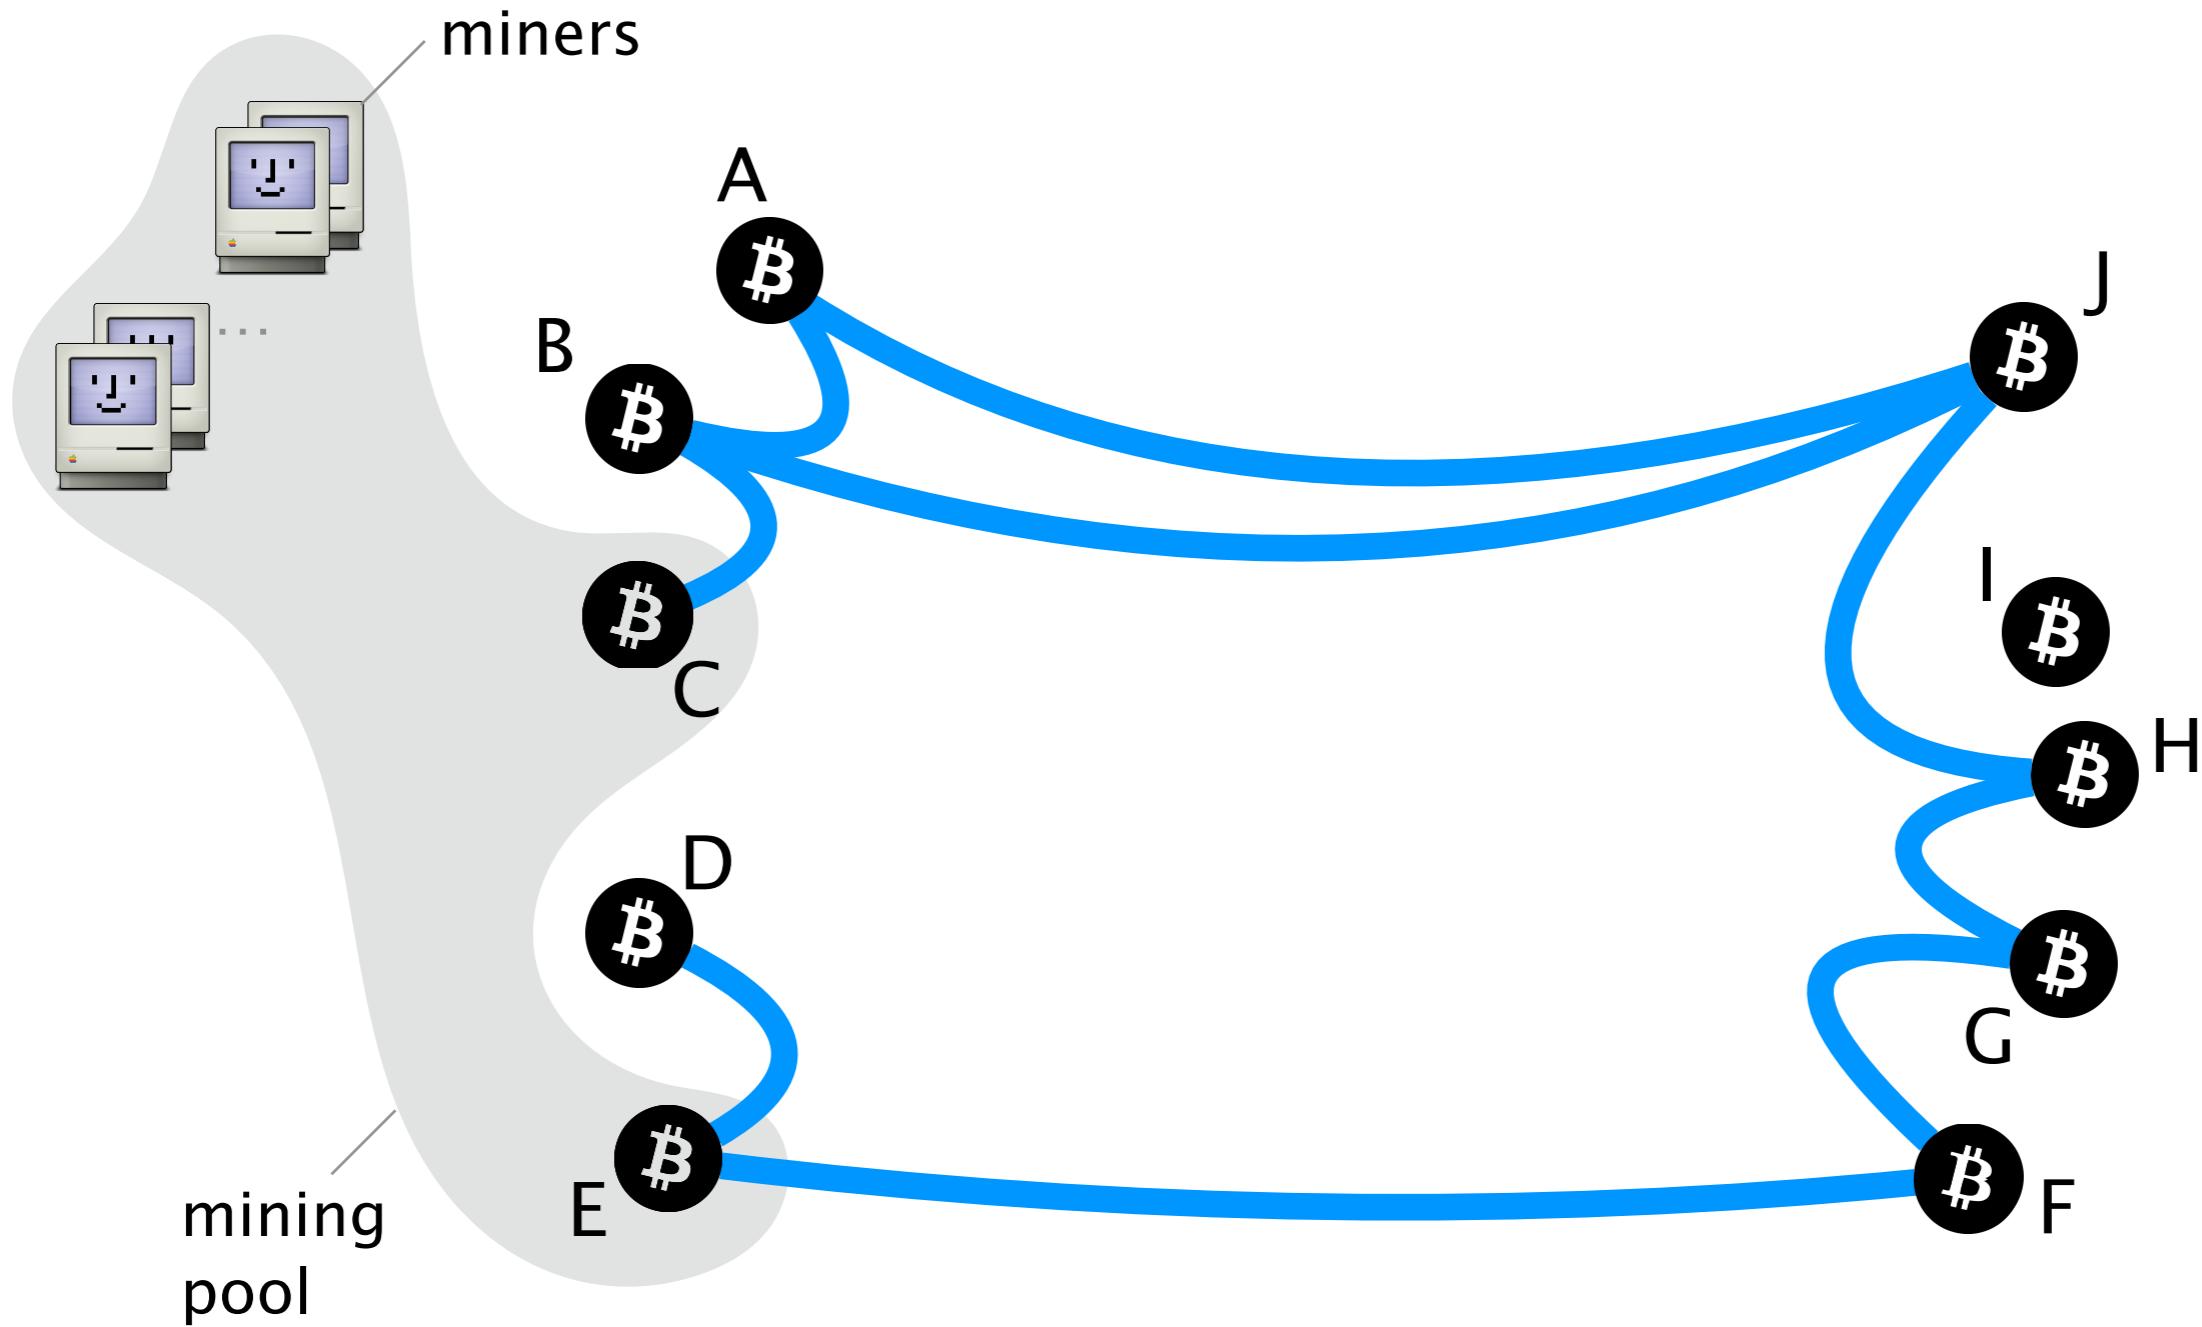

# The Blockchain is a chain of Blocks

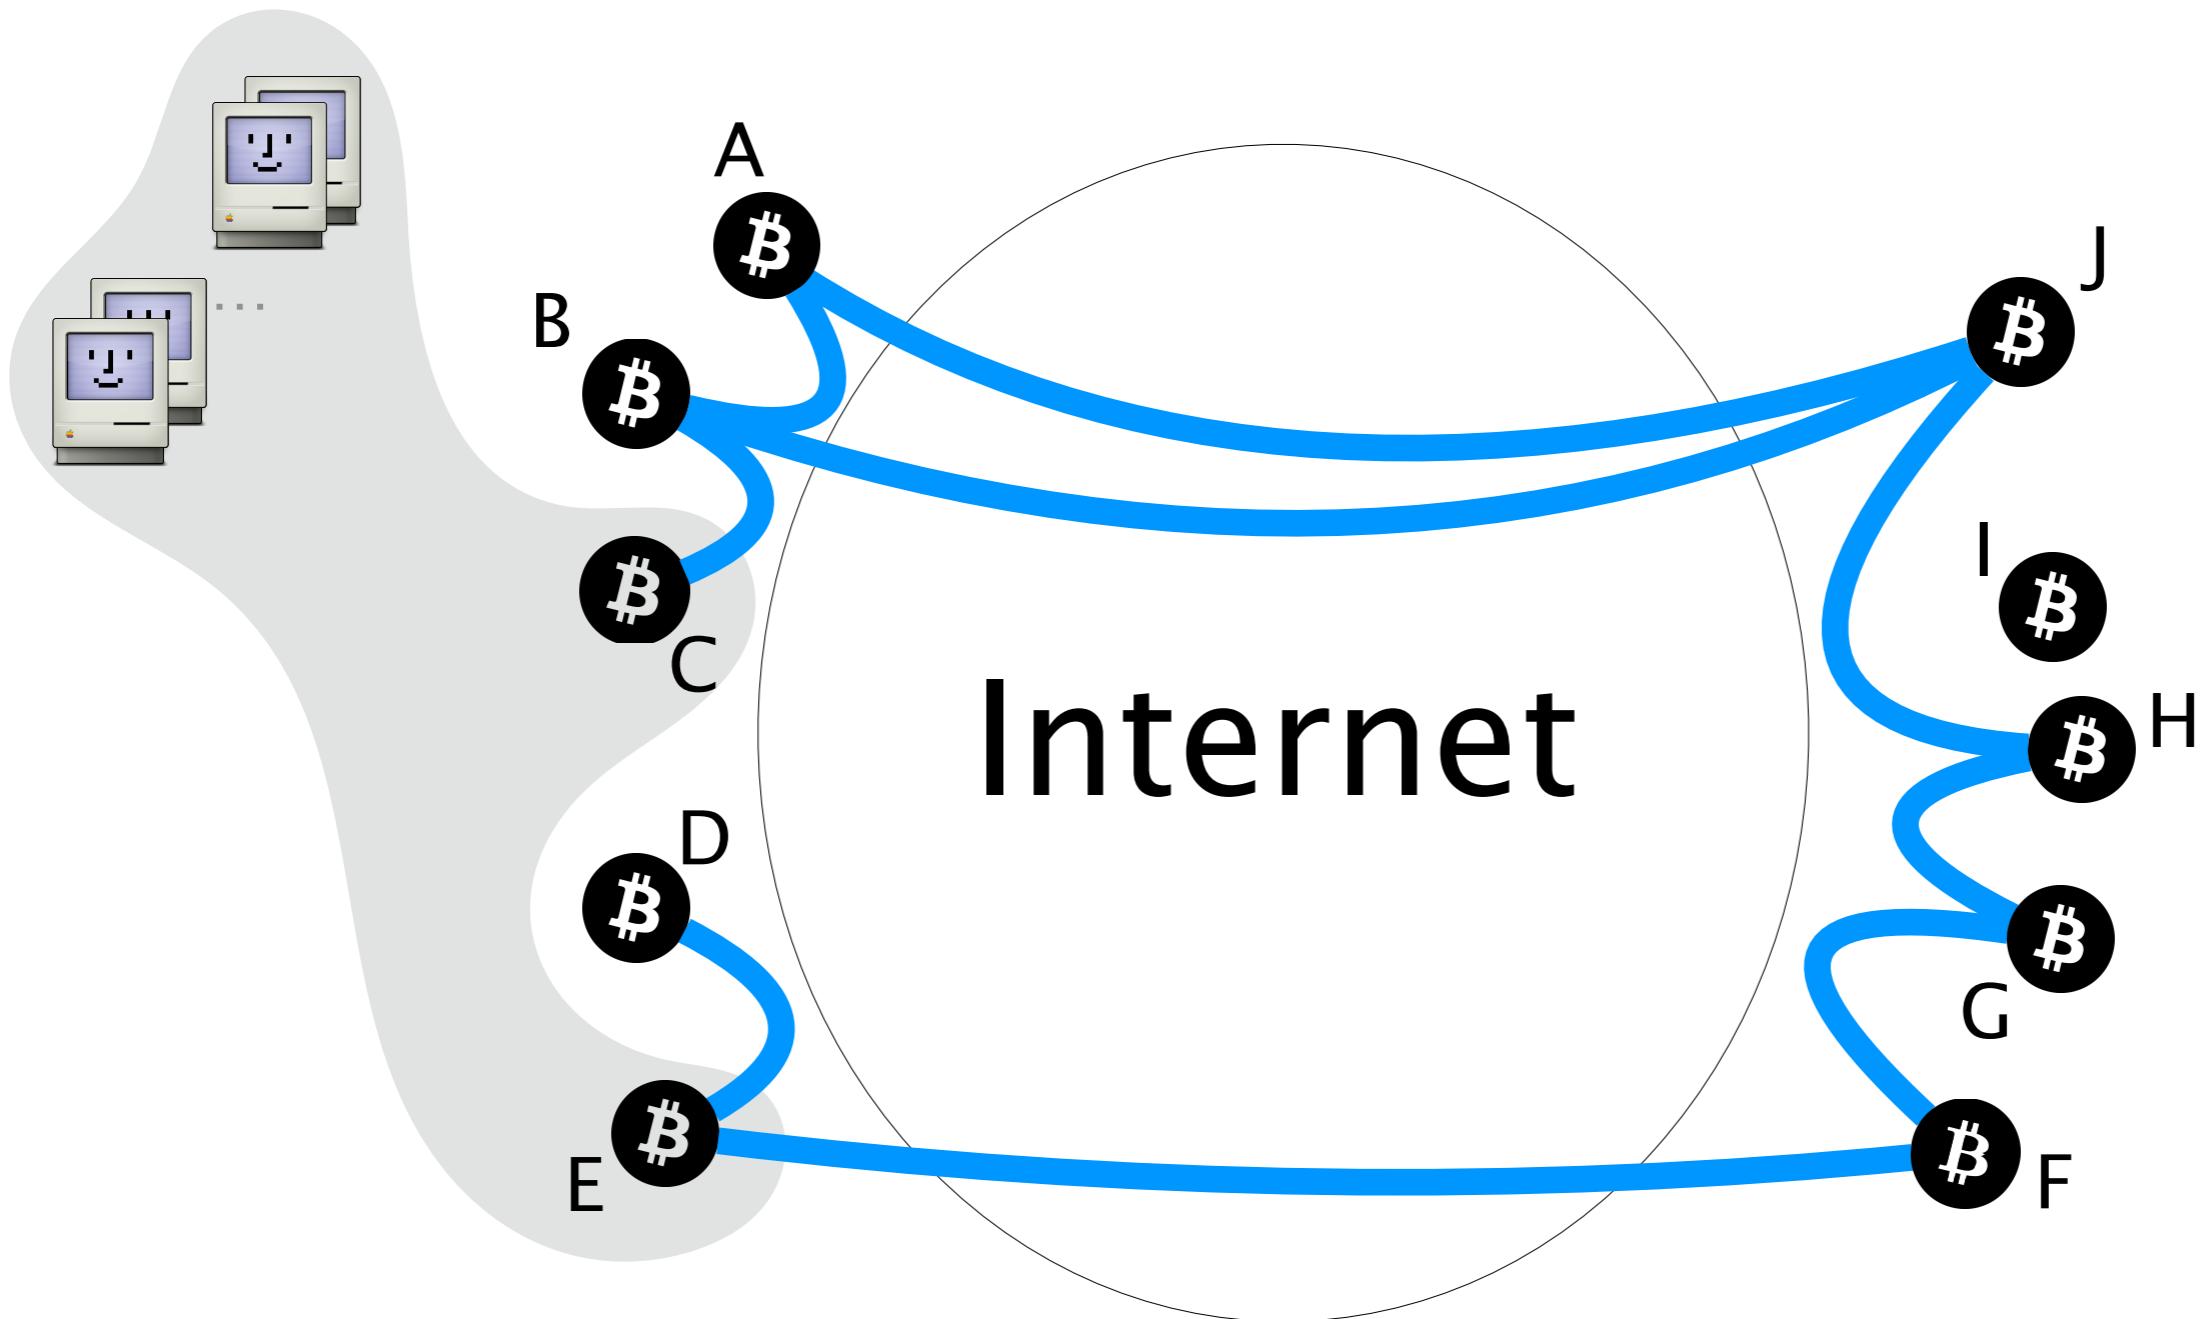

# The Blockchain is extended by miners

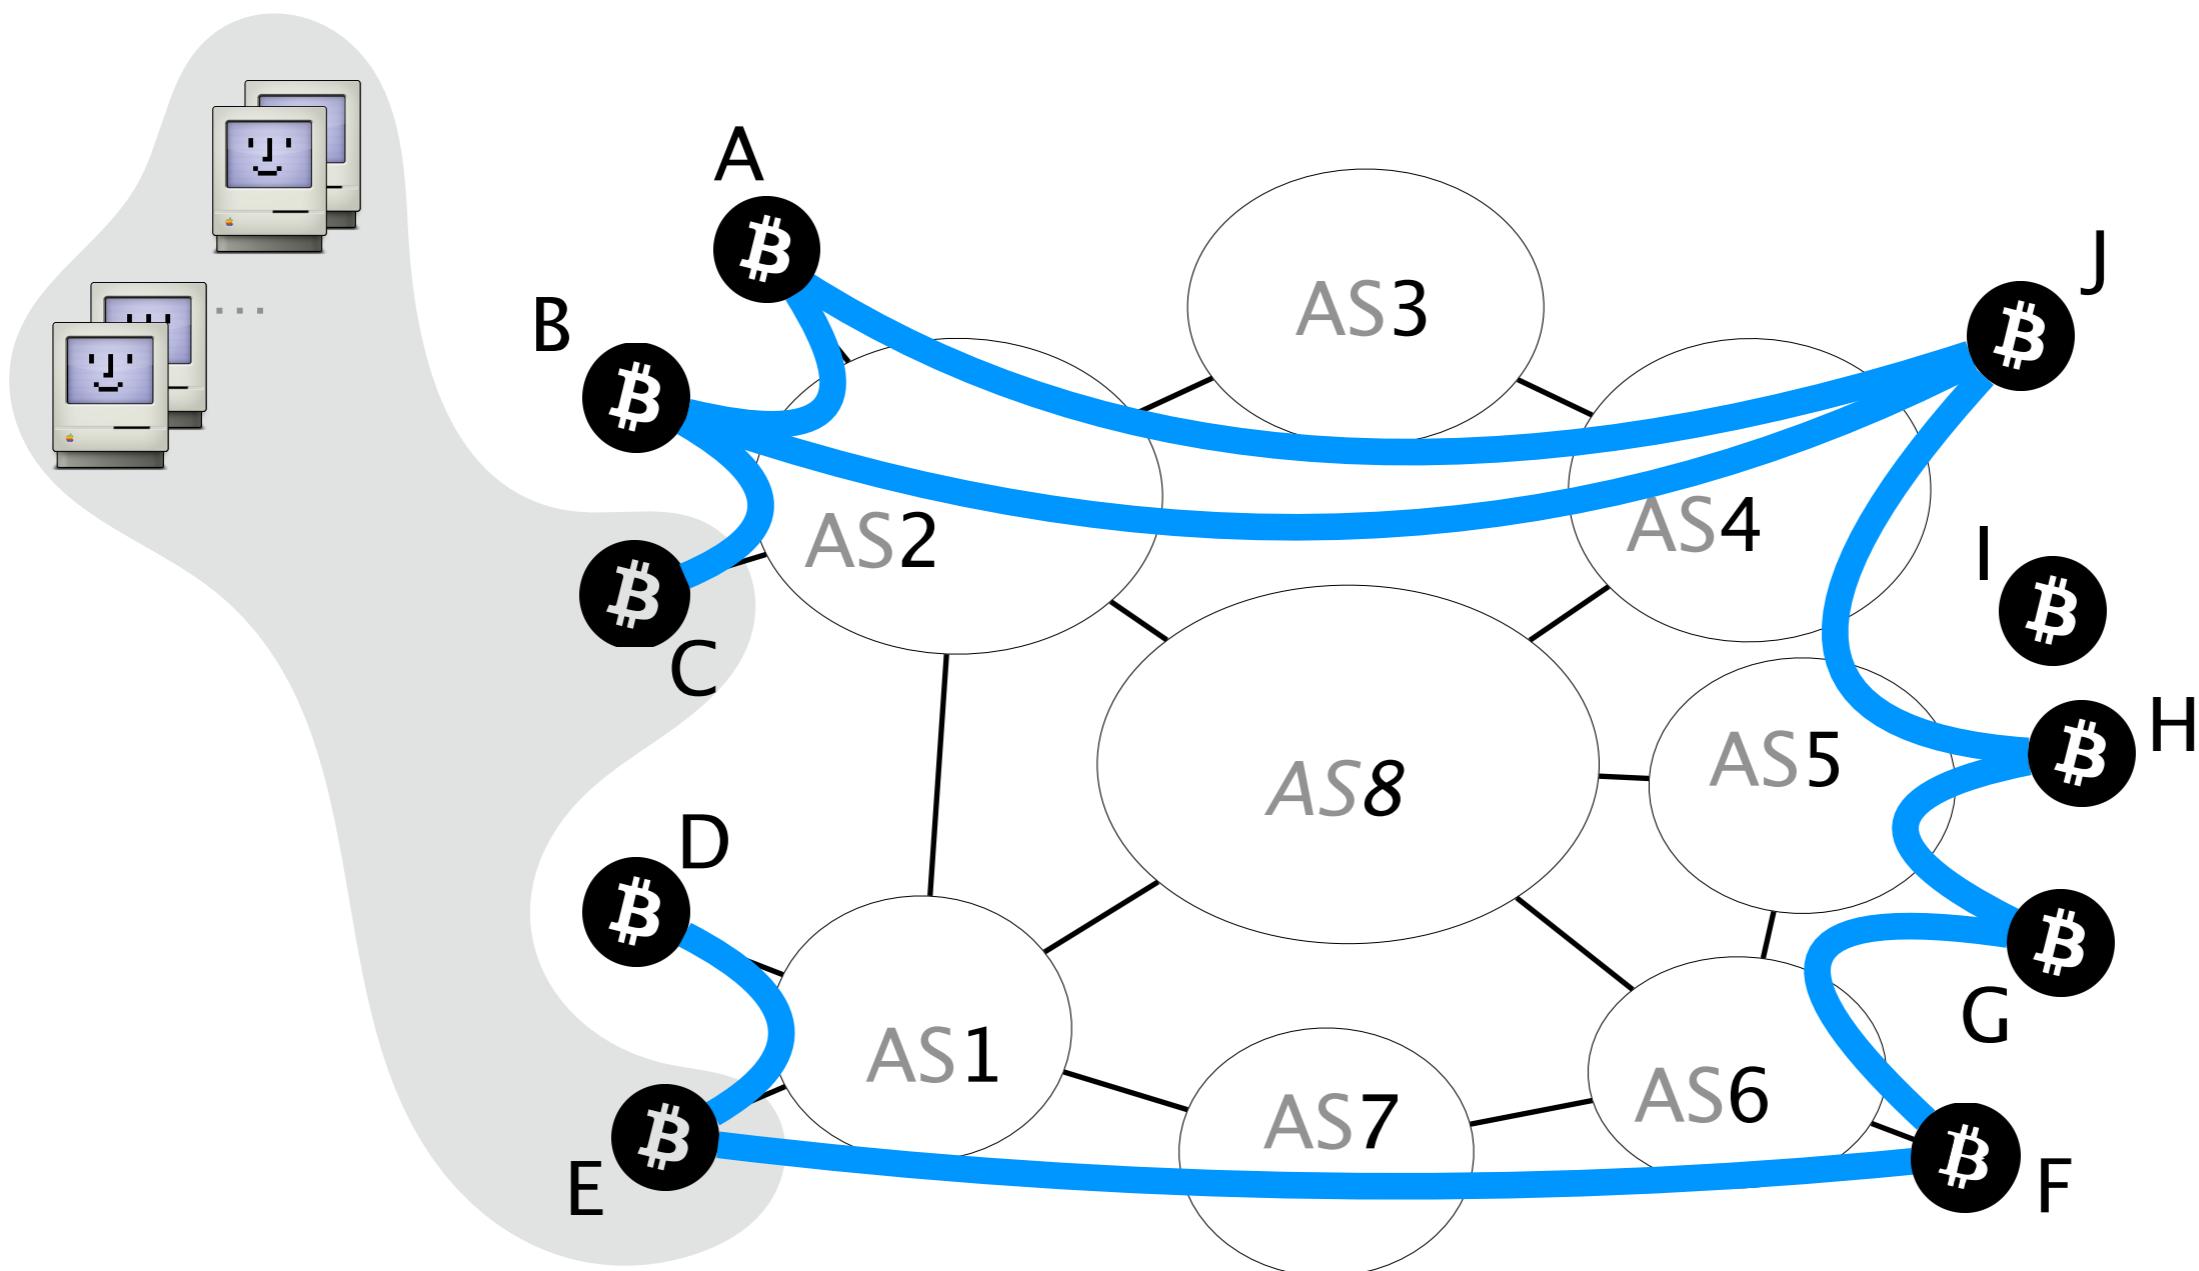

Miners are grouped in **mining pools**

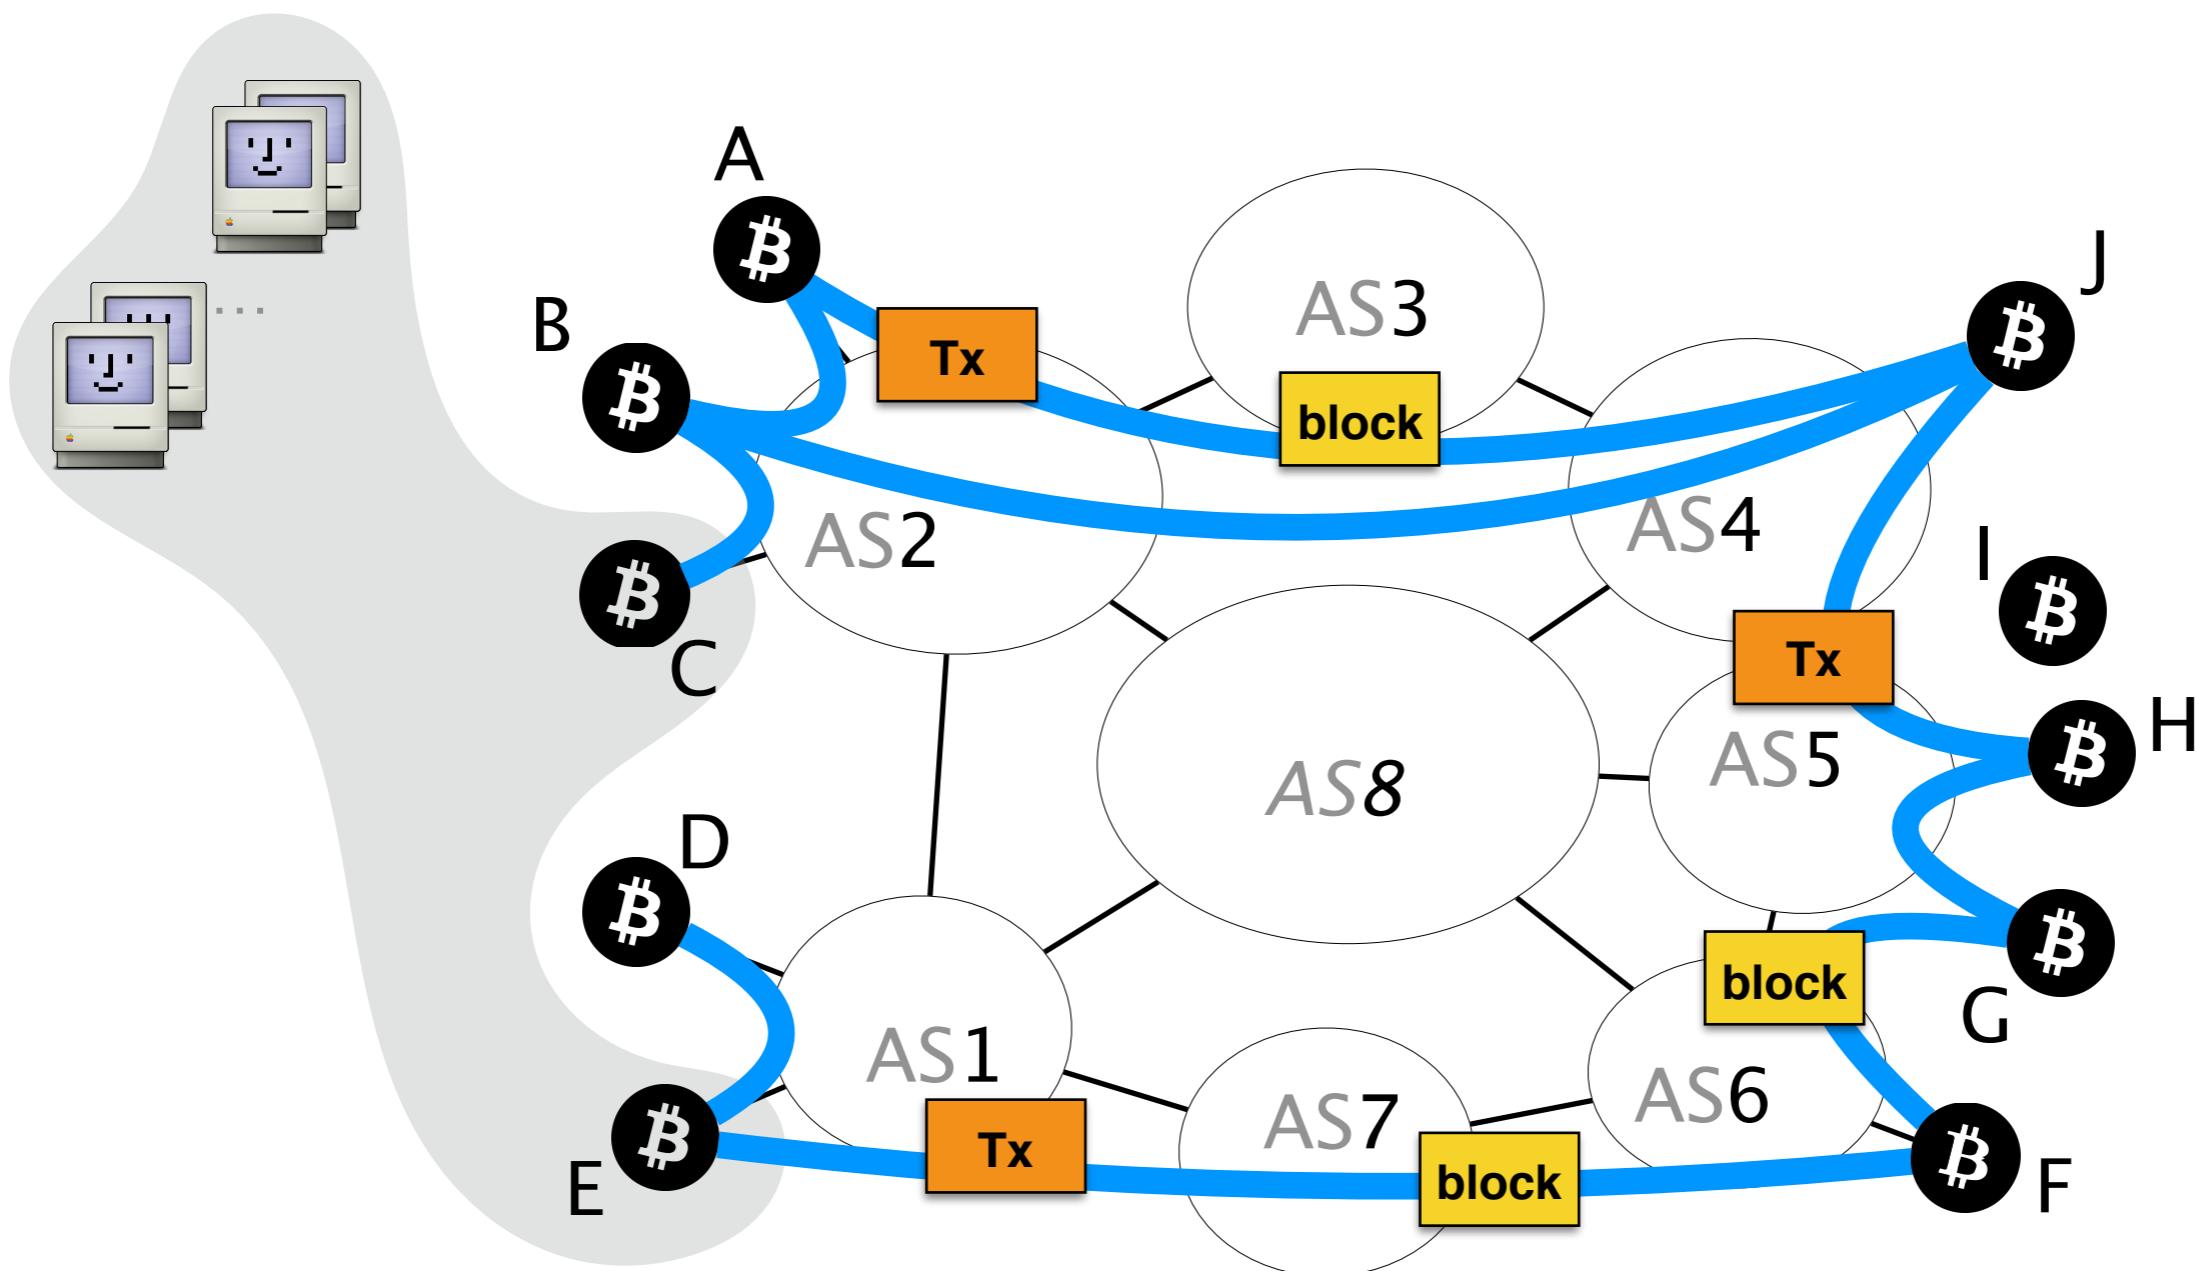

Bitcoin connections are routed over the Internet

The Internet is composed of Autonomous Systems (ASes).  
BGP computes the **forwarding path** across them

Bitcoin messages are propagated **unencrypted** and **without any integrity guarantees**

# Hijacking Bitcoin

## Routing Attacks on Cryptocurrencies

**Background**

BGP & Bitcoin

2

**Partitioning attack**  
splitting the network

**Delay attack**

slowing the network down

**Countermeasures**

short-term & long-term

The goal of a partitioning attack is to split  
the Bitcoin network into **two disjoint components**

# The impact of such an attack is worrying

Denial of Service

Revenue Loss

Double spending

# The impact of such an attack is worrying

Denial of Service

Revenue Loss

Double spending

Bitcoin clients and wallets cannot secure or propagate transactions

# The impact of such an attack is worrying

Denial of Service

**Revenue Loss**

Double spending

Blocks in component with  
less mining power are discarded

# The impact of such an attack is worrying

Denial of Service

Revenue Loss

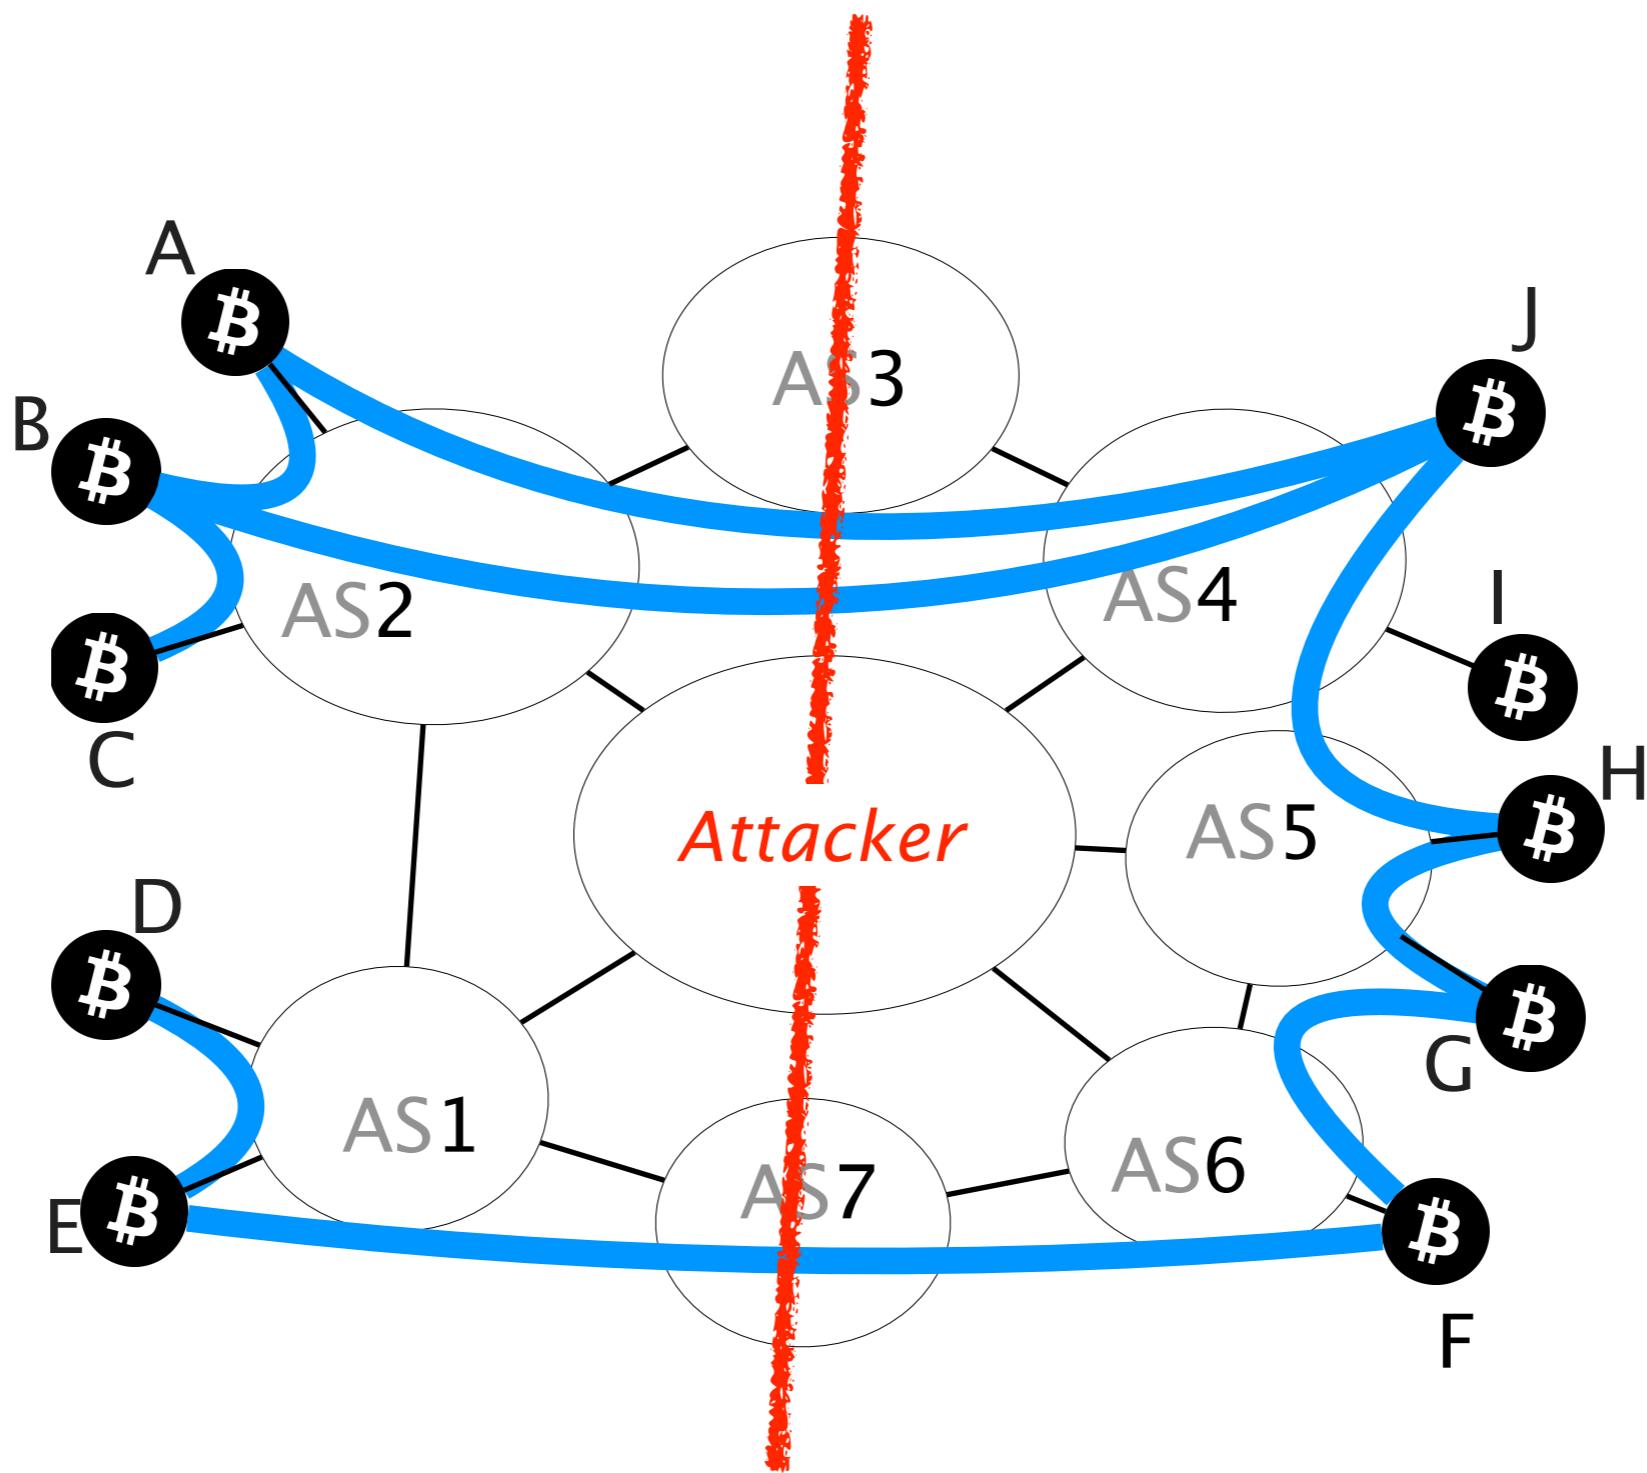

**Double spending**

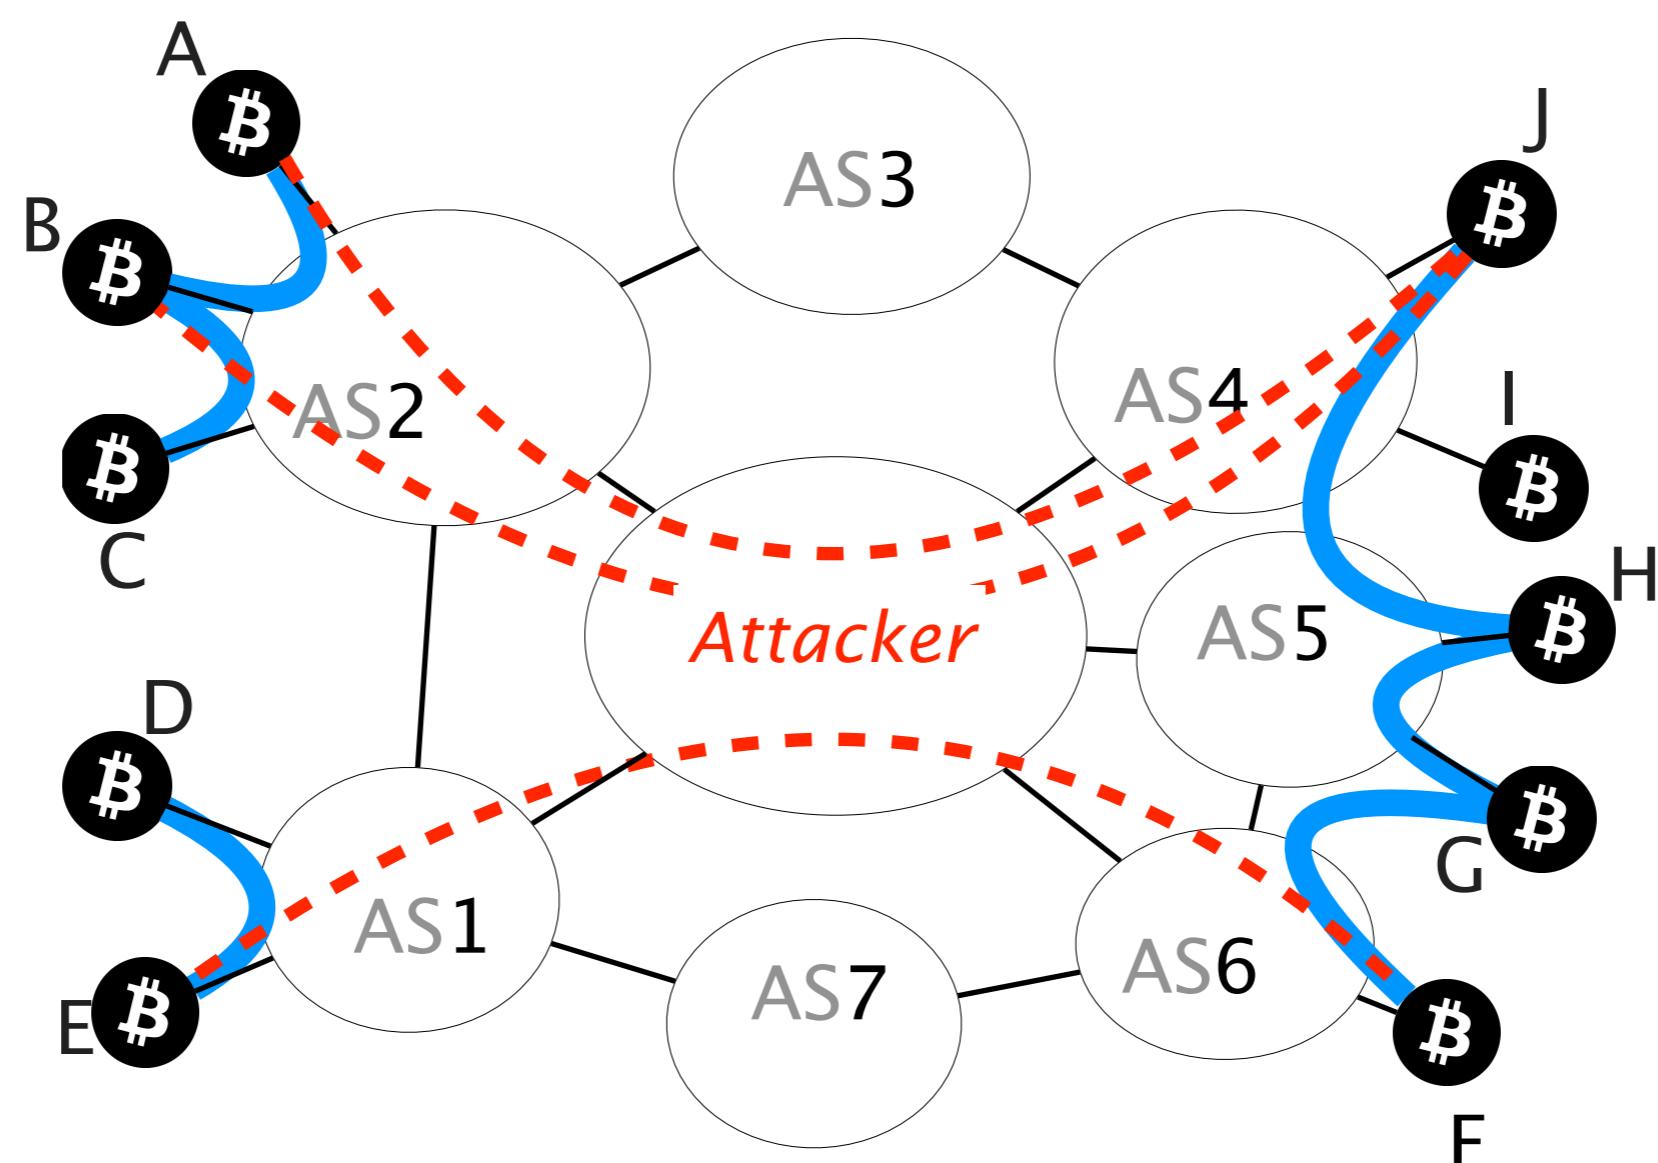

Transactions in components with less mining power can be reverted

# How does the attack work?

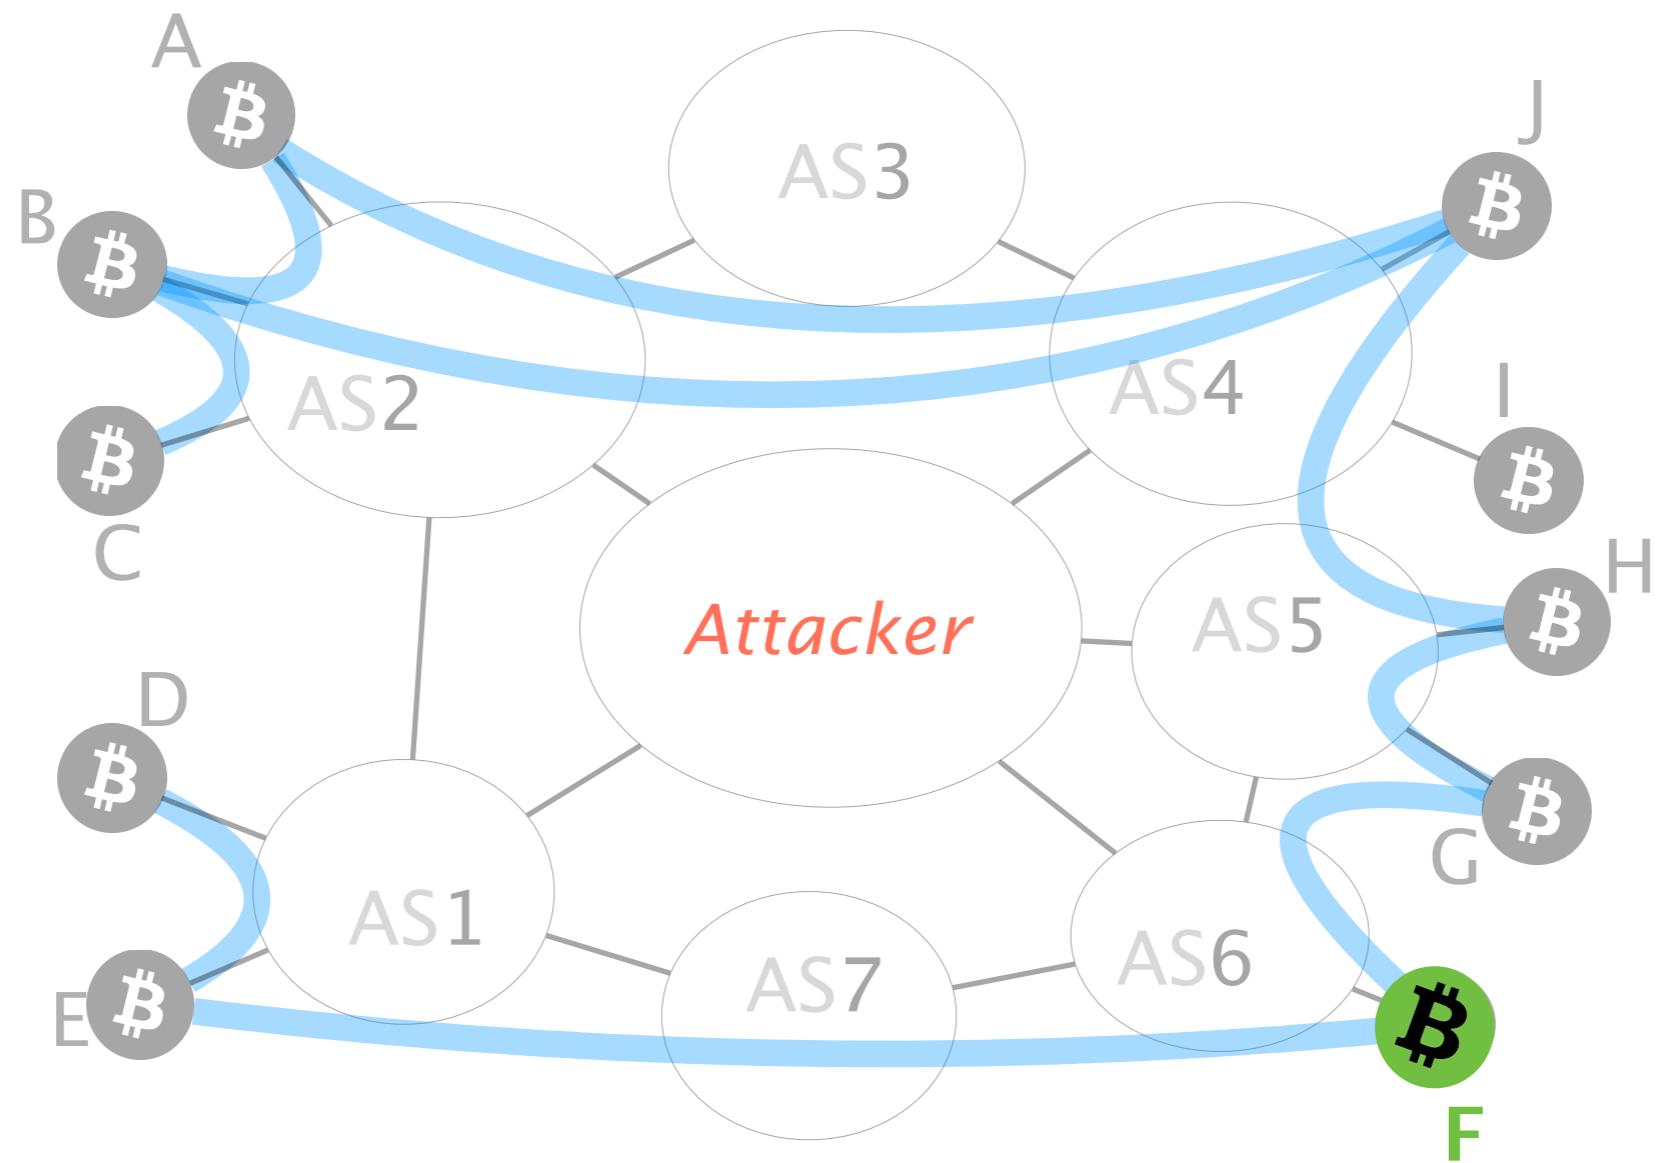

Let's say an attacker wants to **partition** the network  
into the **left** and **right** side

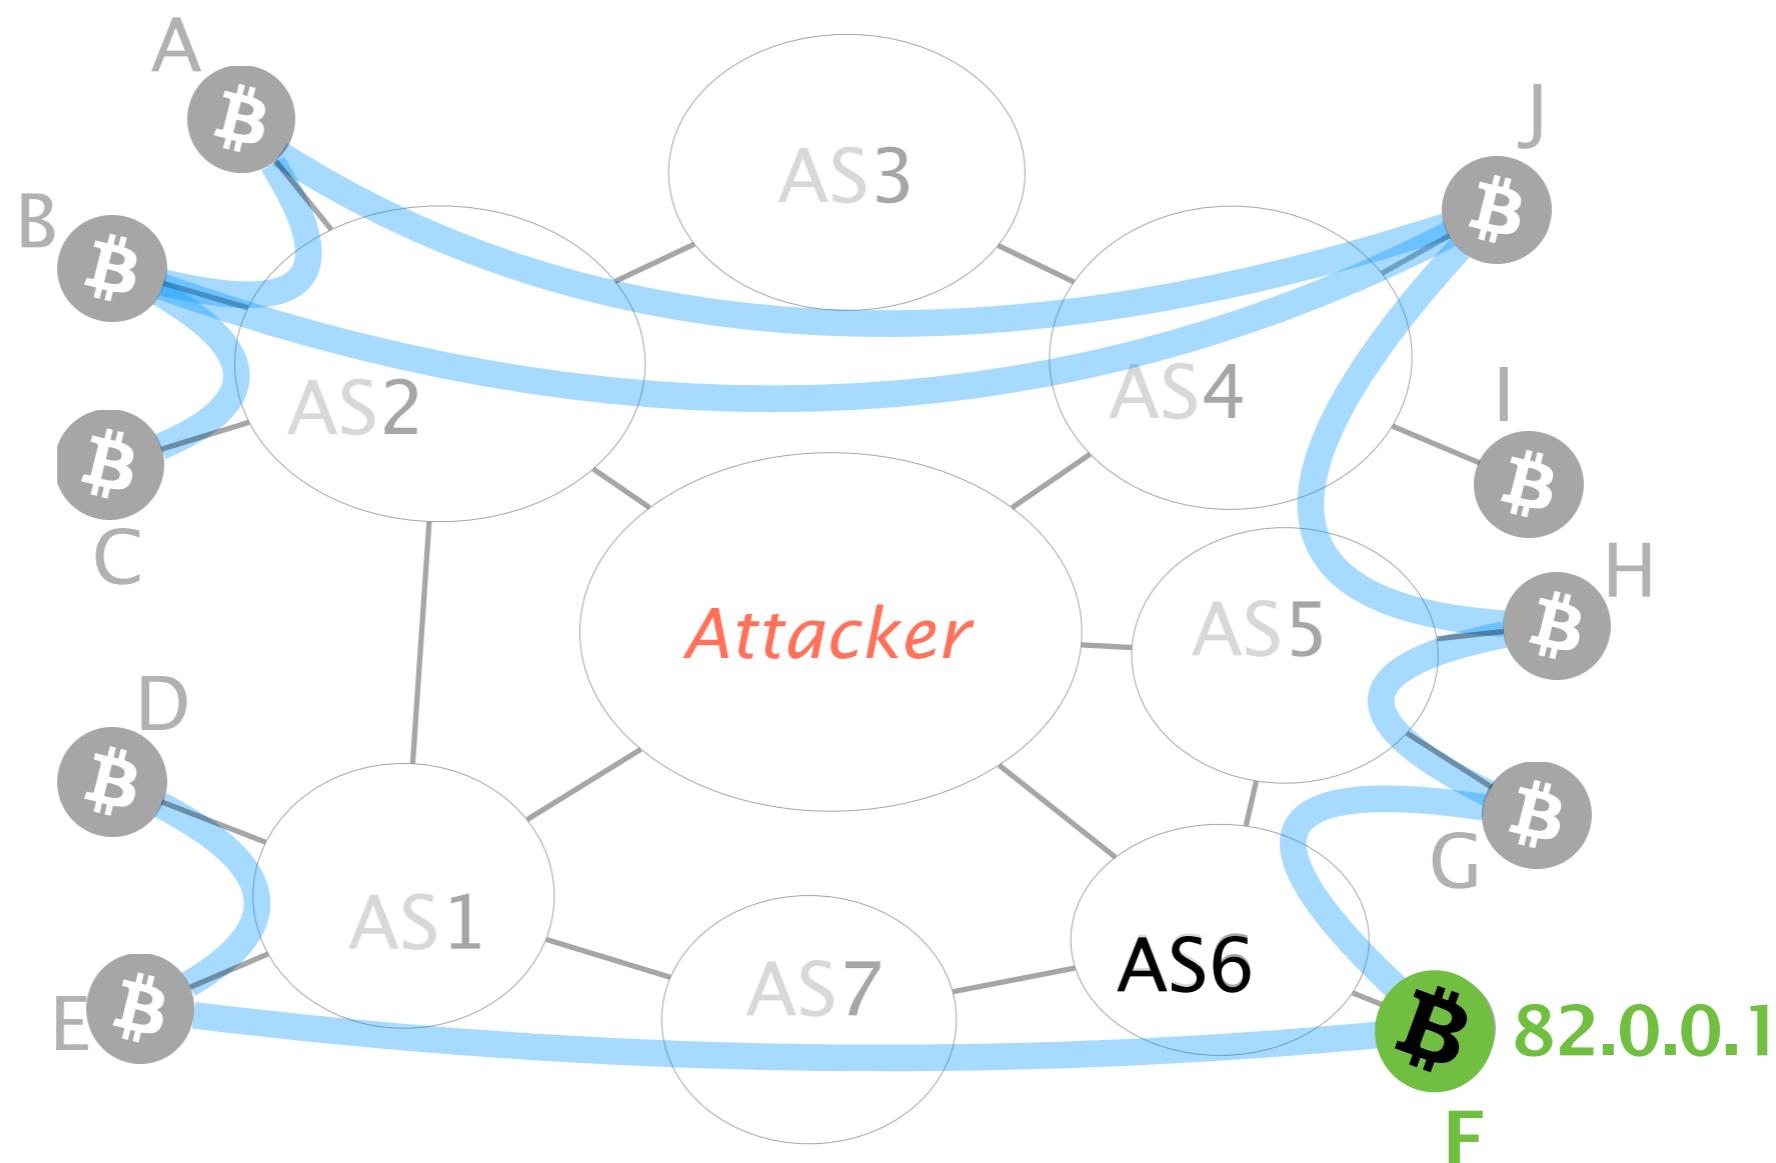

For doing so, the attacker will manipulate BGP routes to intercept any traffic to the nodes in the right

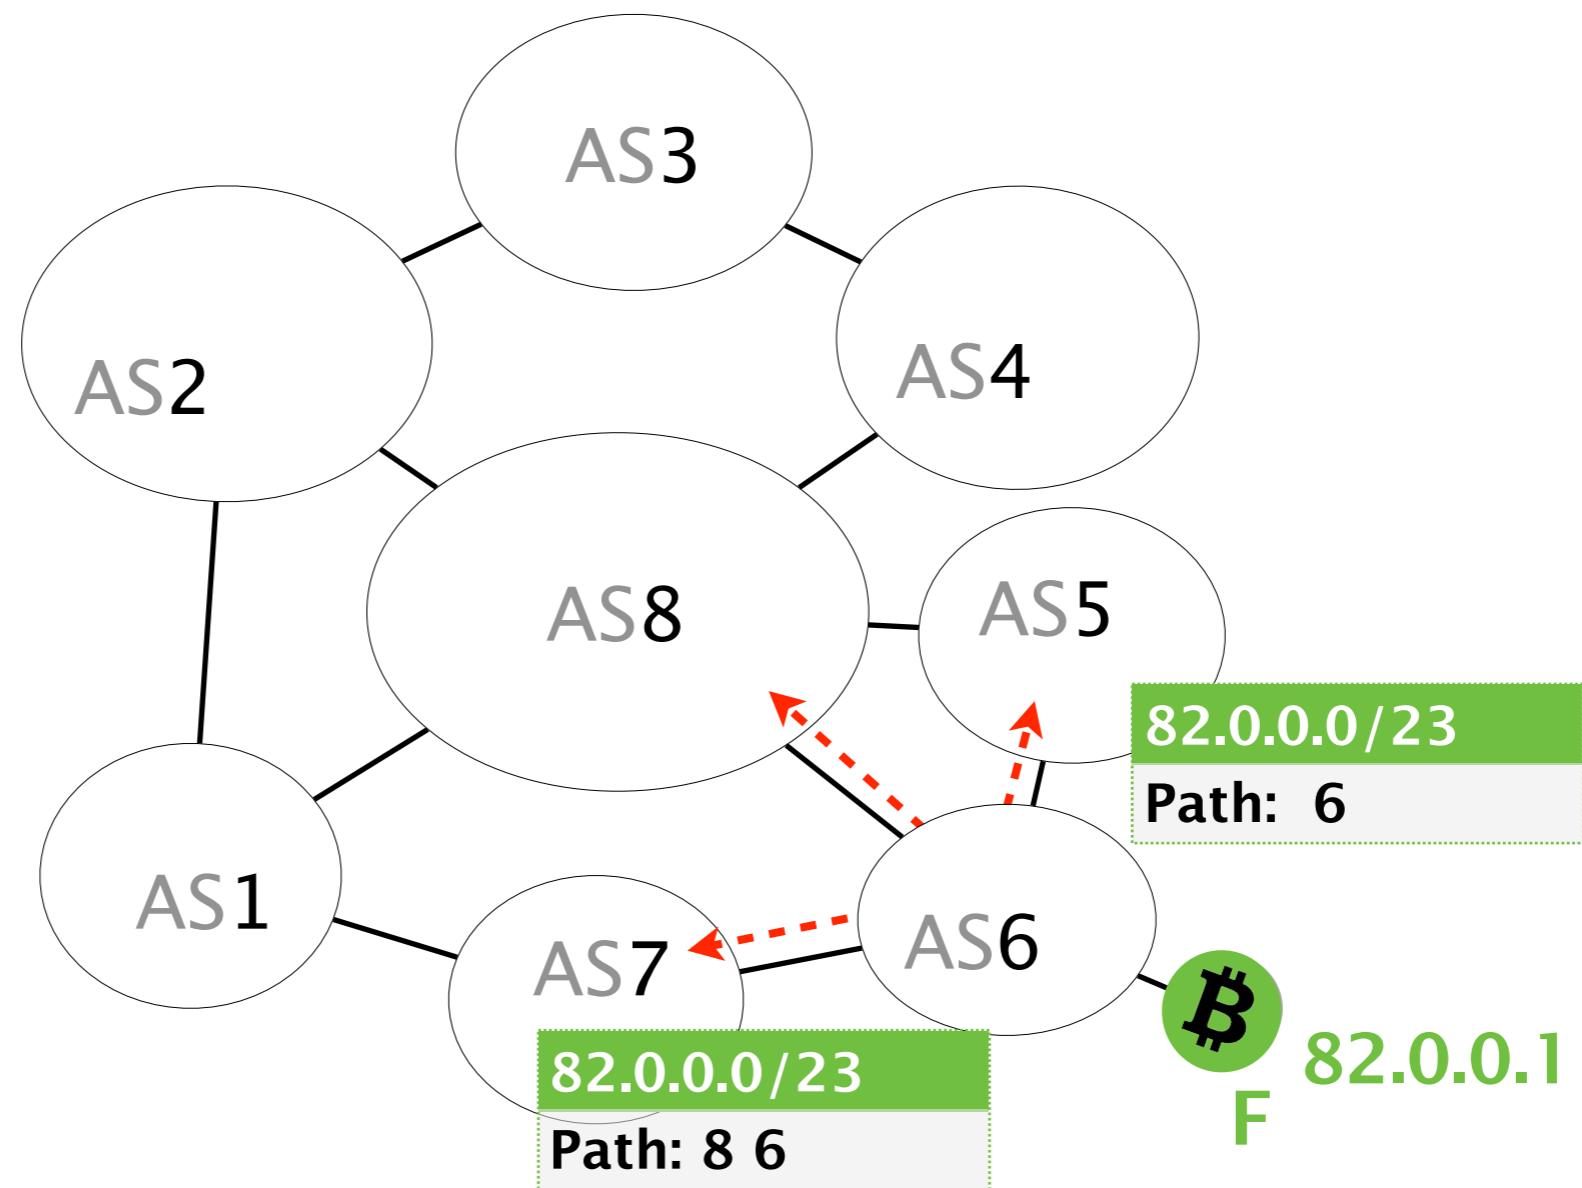

Let us focus on node F

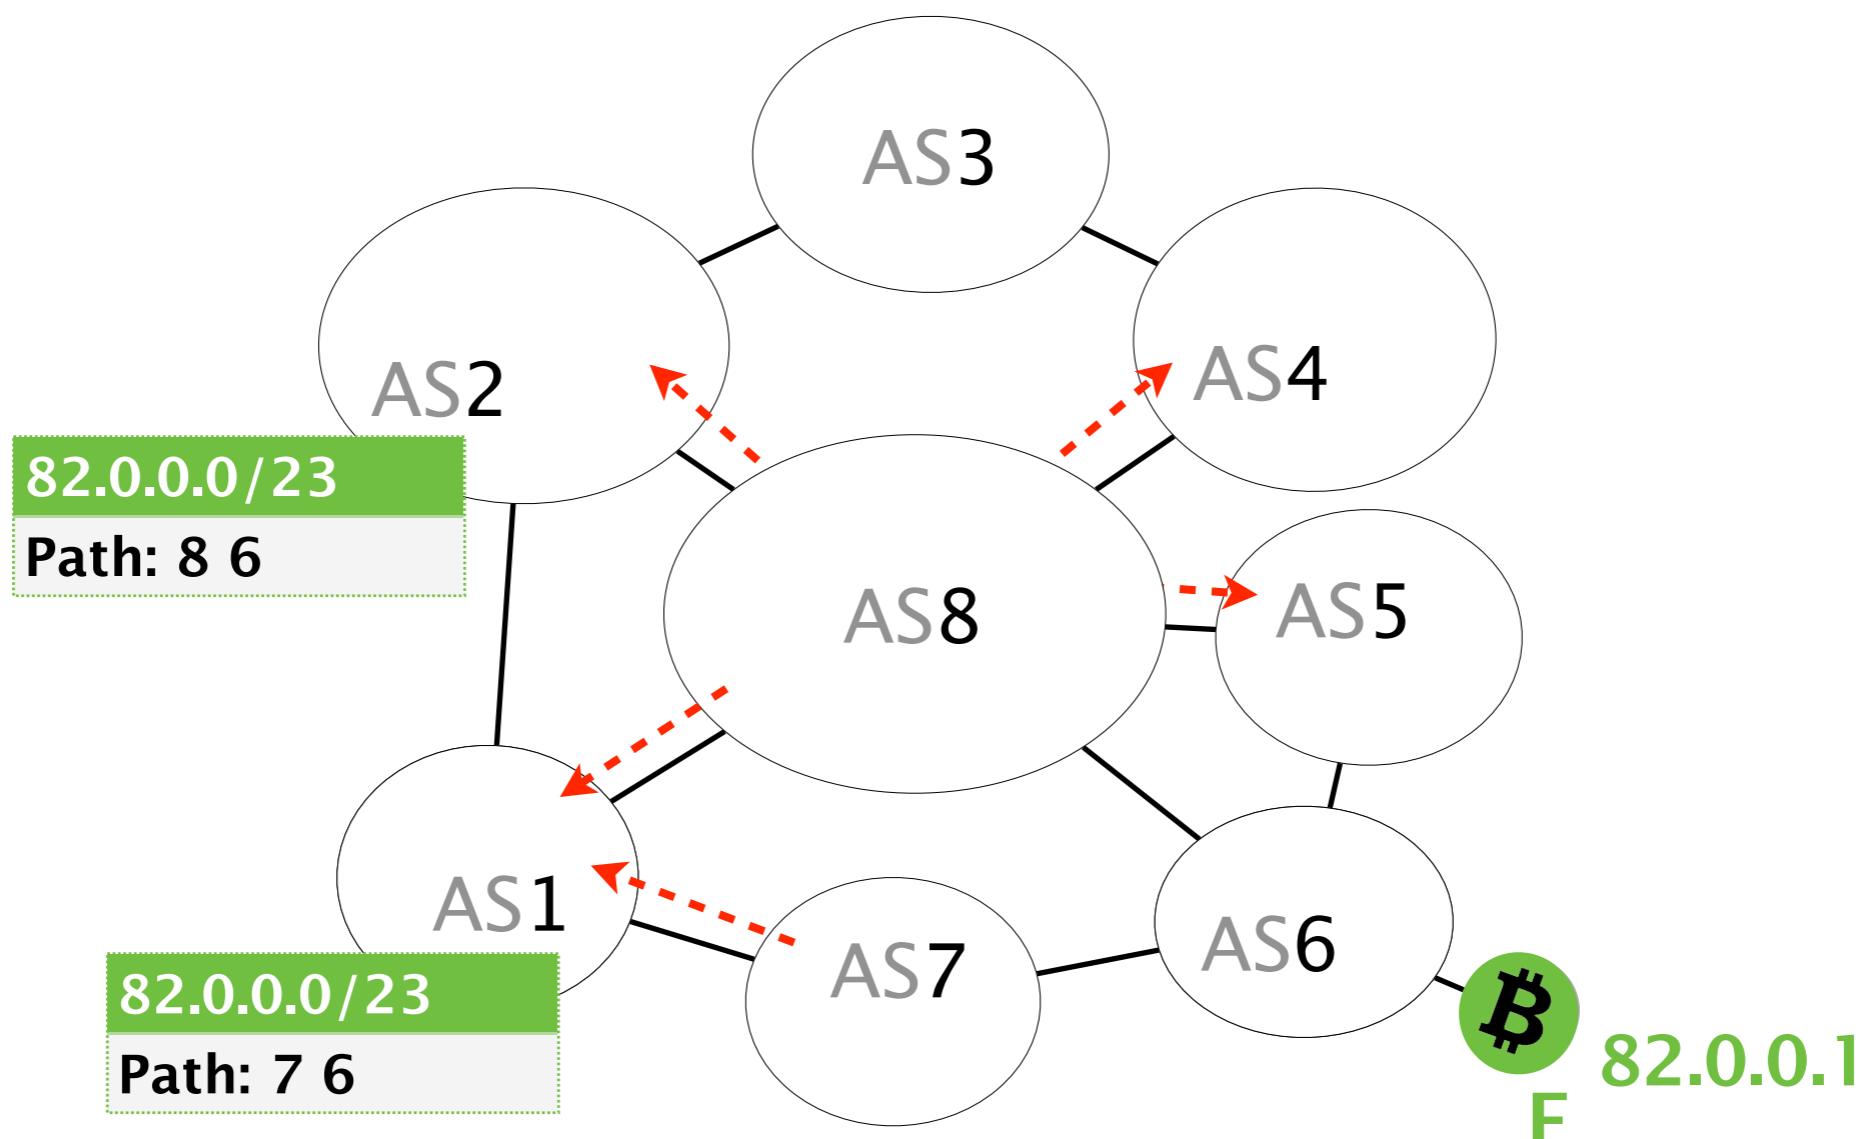

F's provider (AS6) is responsible for IP prefix

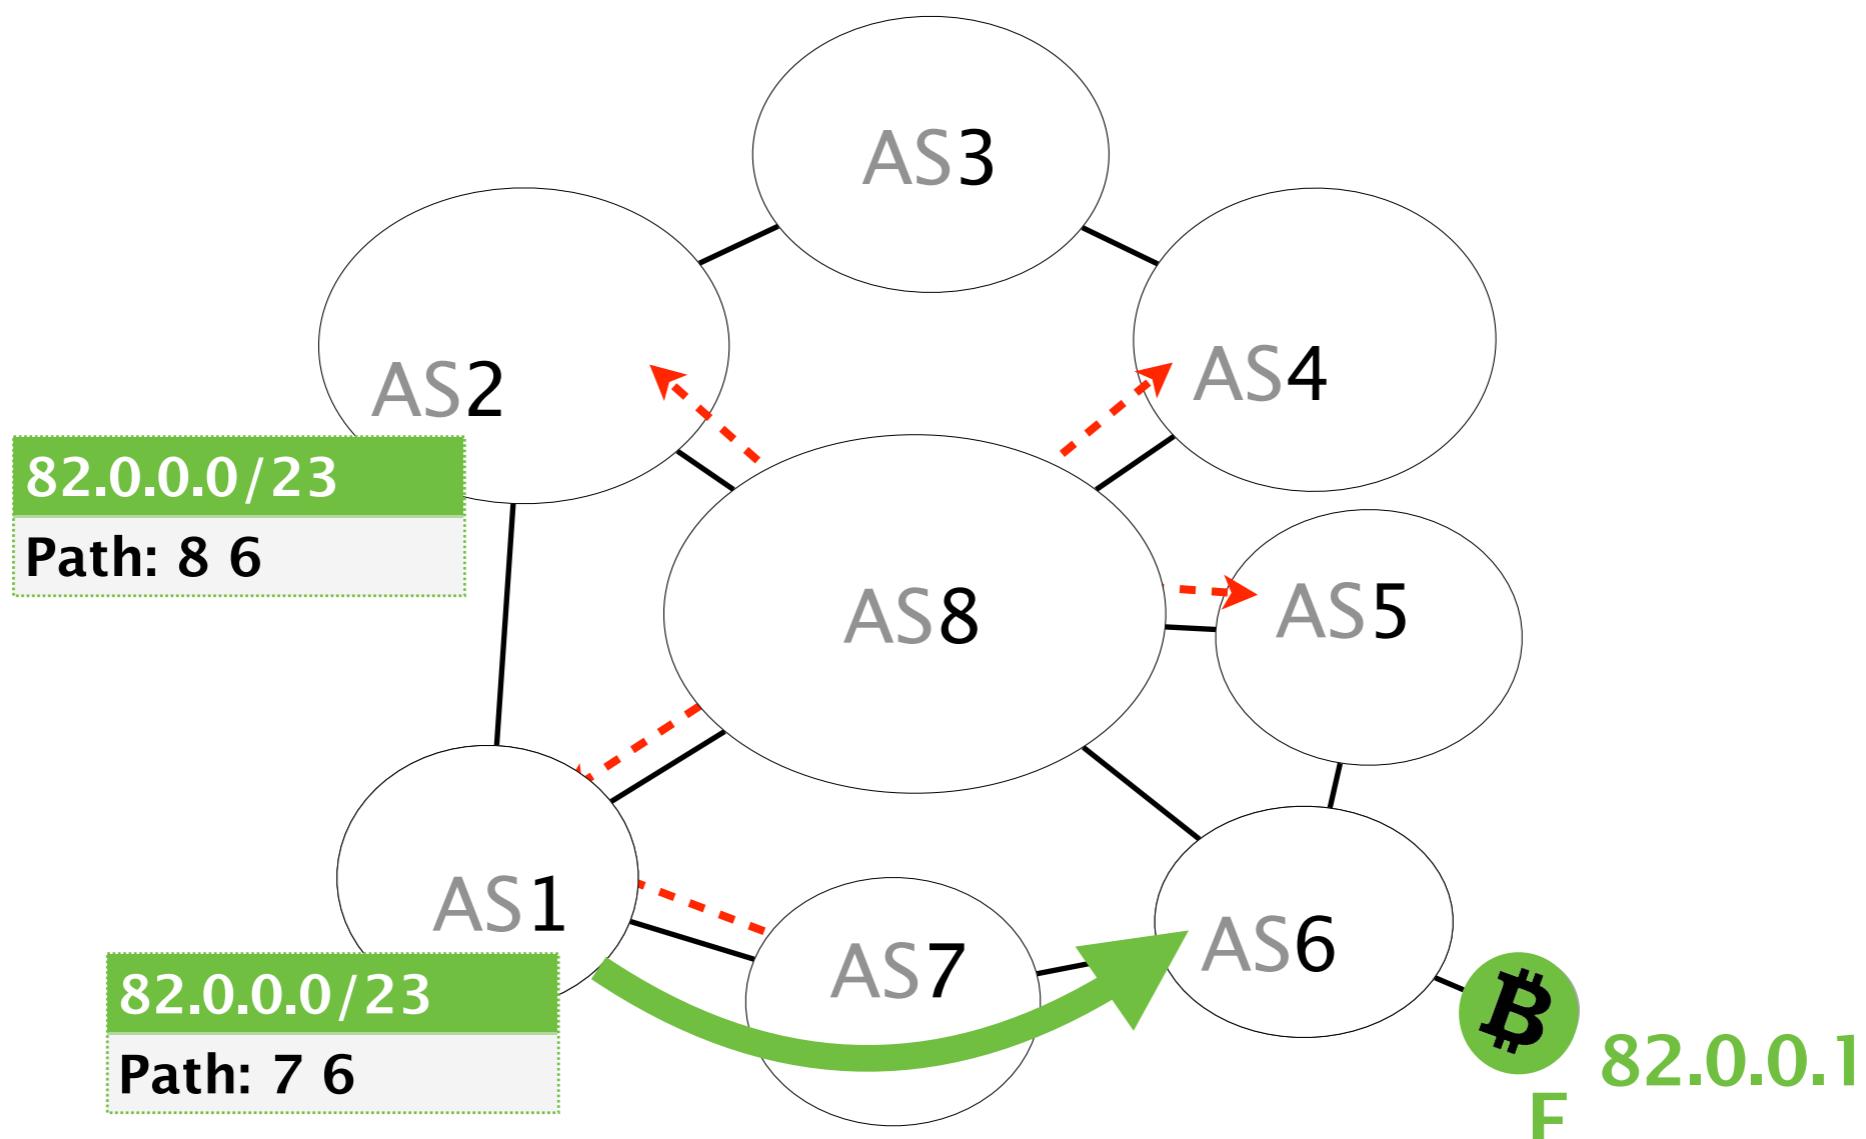

# AS6 will create a BGP advertisement

AS6's advertisement is propagated AS-by-AS until all ASes in the Internet learn about it

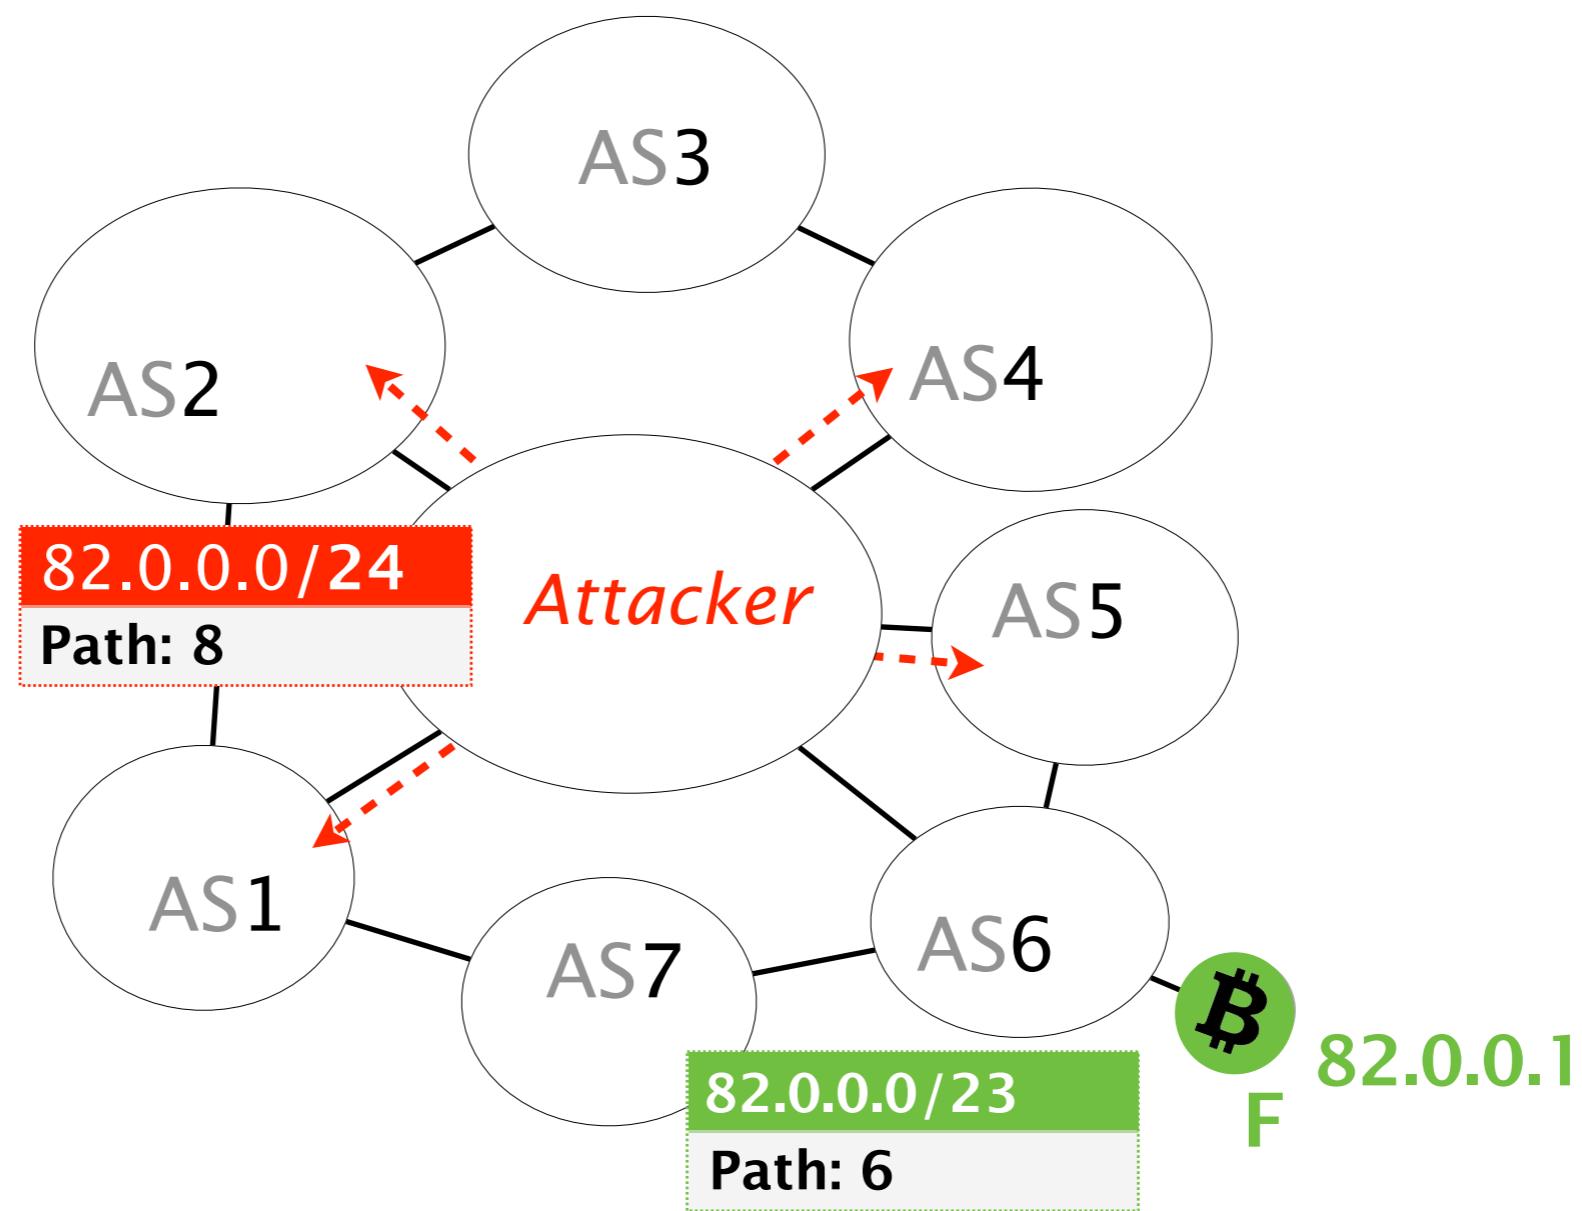

AS6's advertisement is propagated AS-by-AS until all ASes in the Internet learn about it

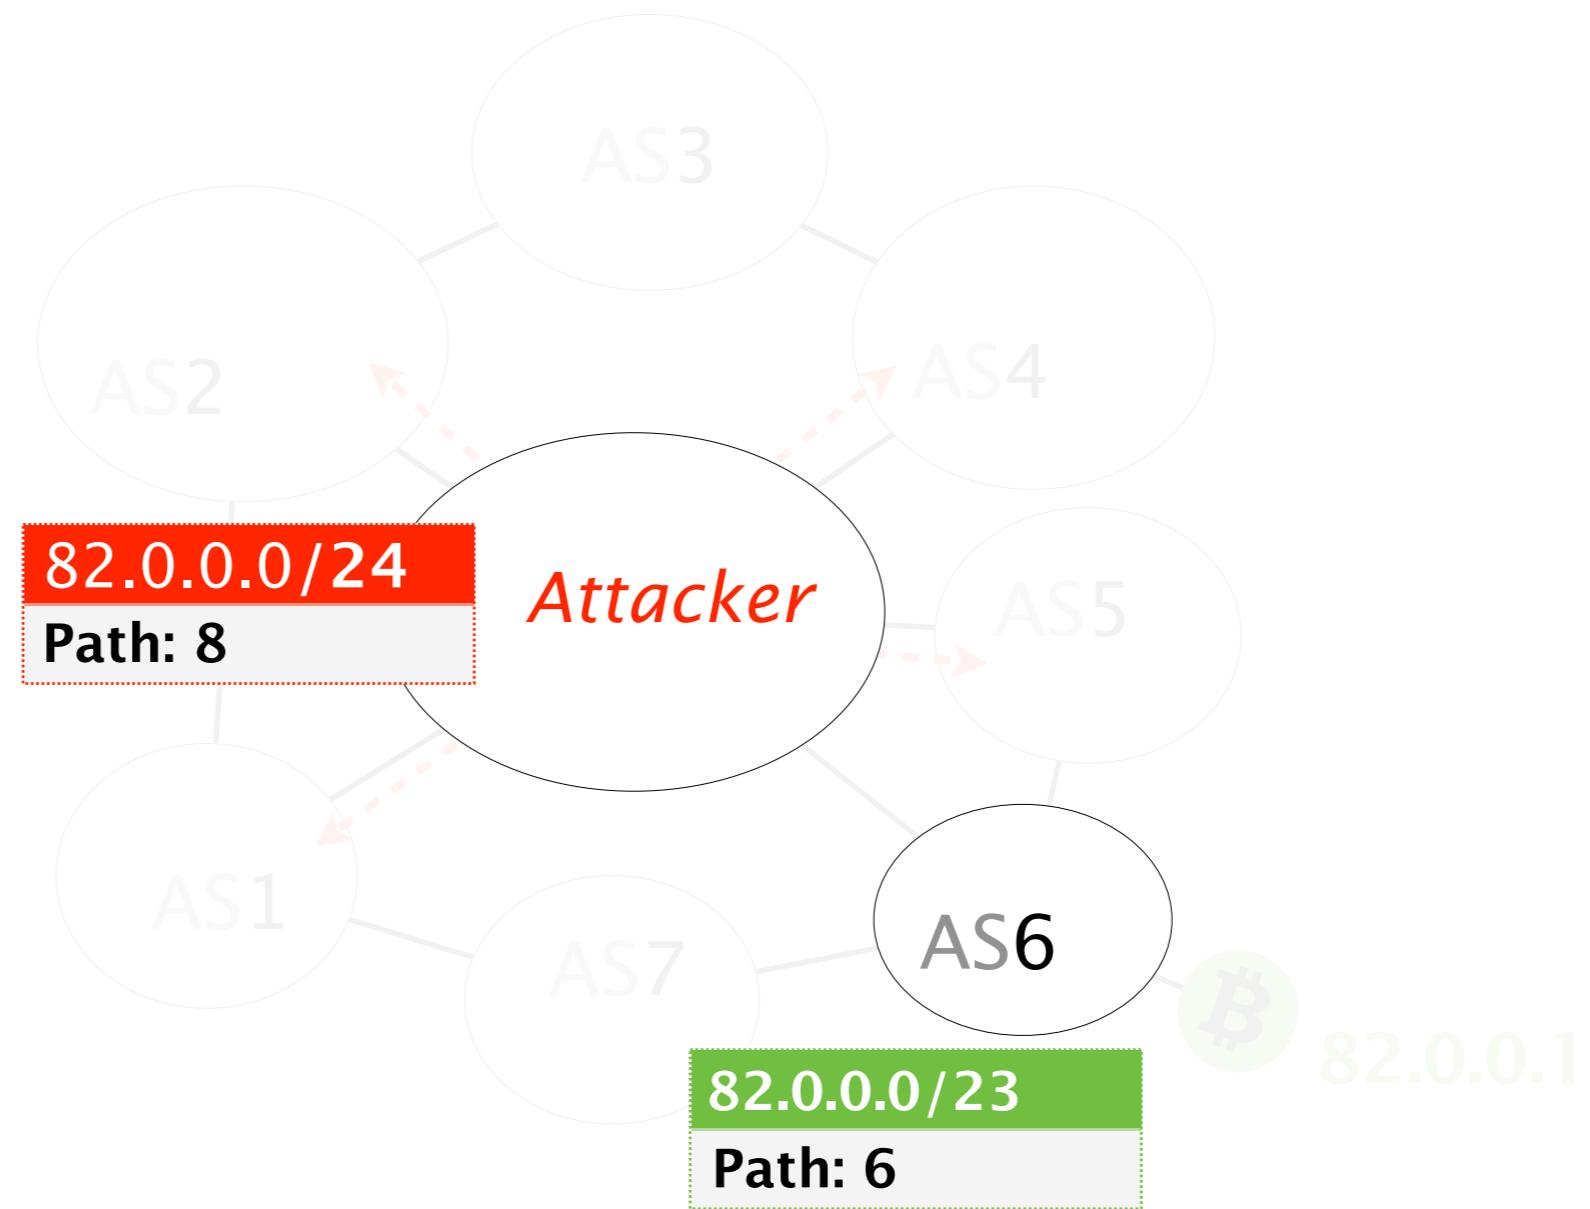

BGP does not check the validity of advertisements,  
meaning any AS can announce any prefix

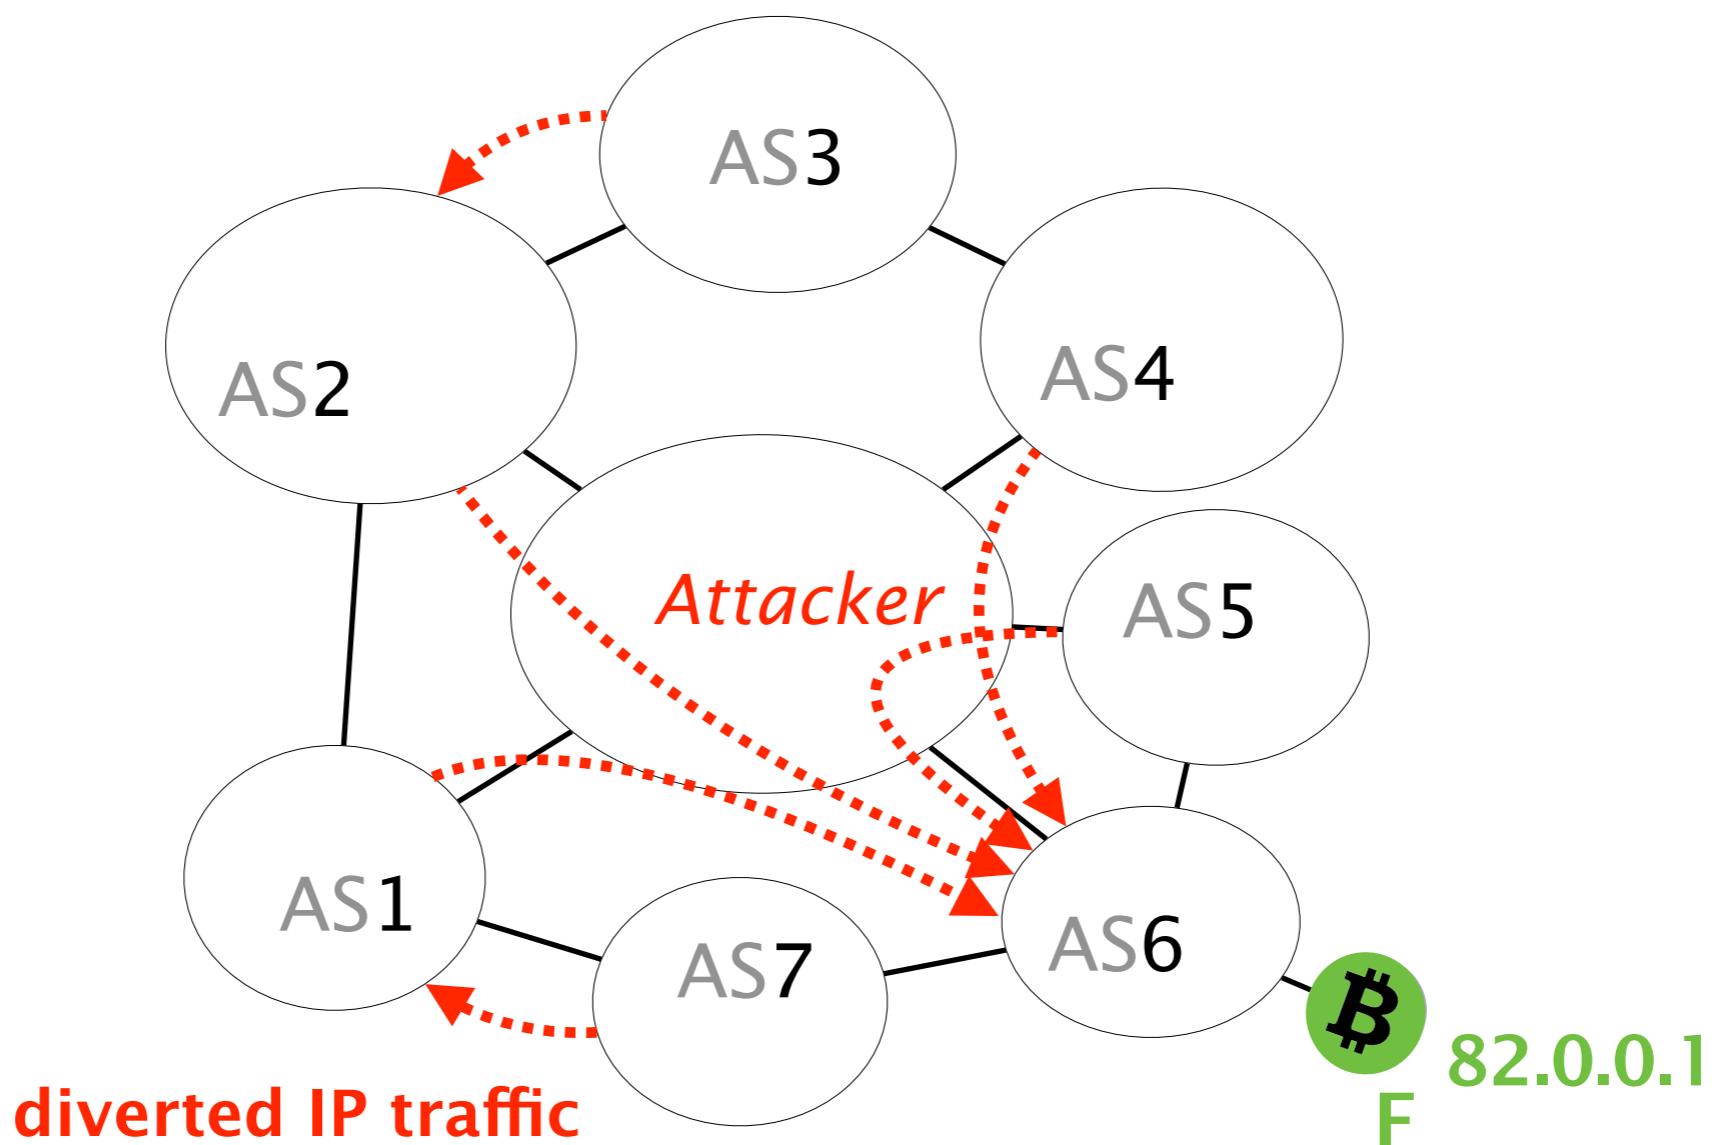

Consider that the attacker advertises a  
more-specific prefix covering F's IP address

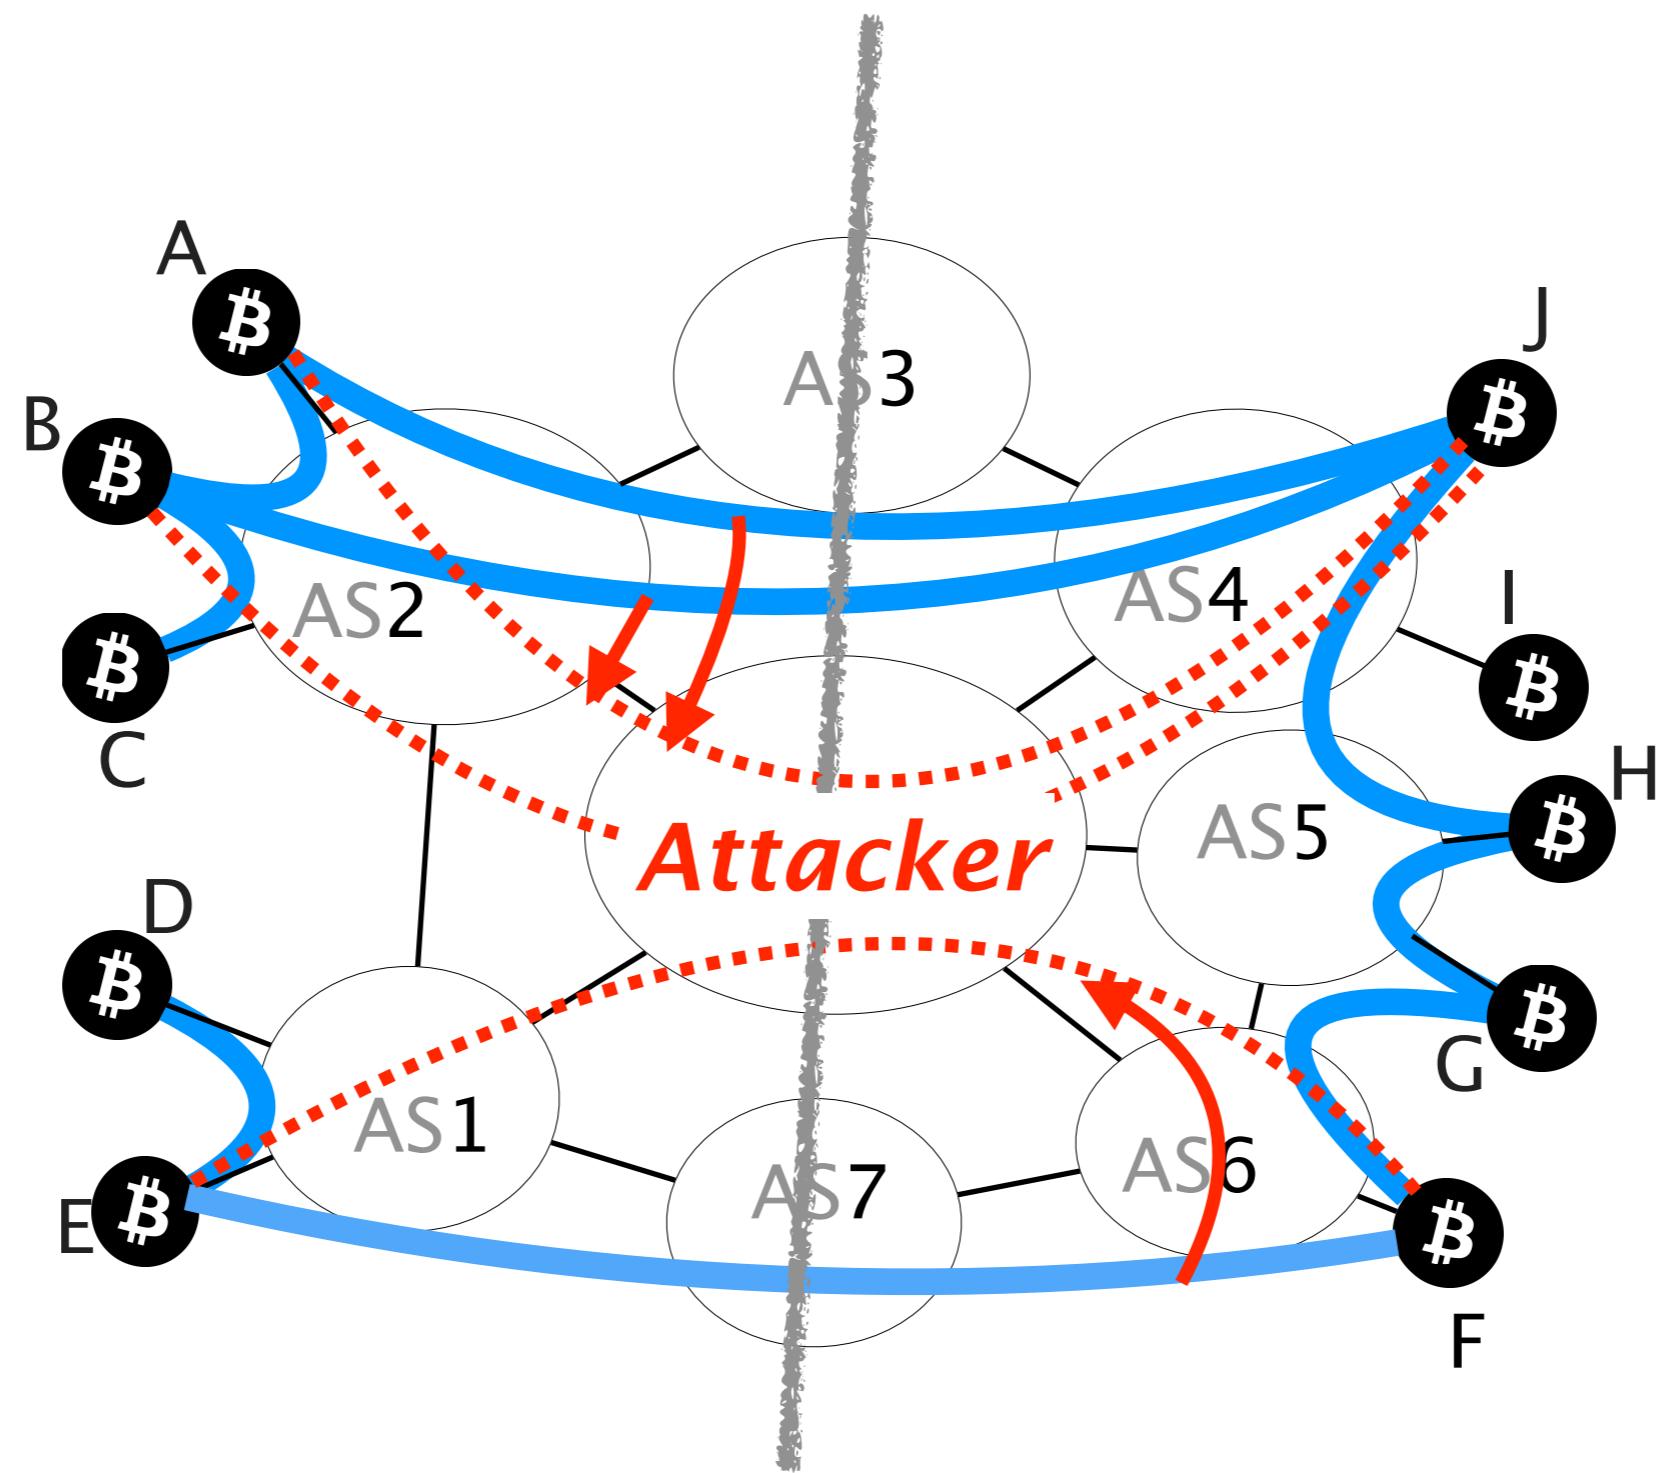

As IP routers prefer more-specific prefixes, the attacker route will be preferred

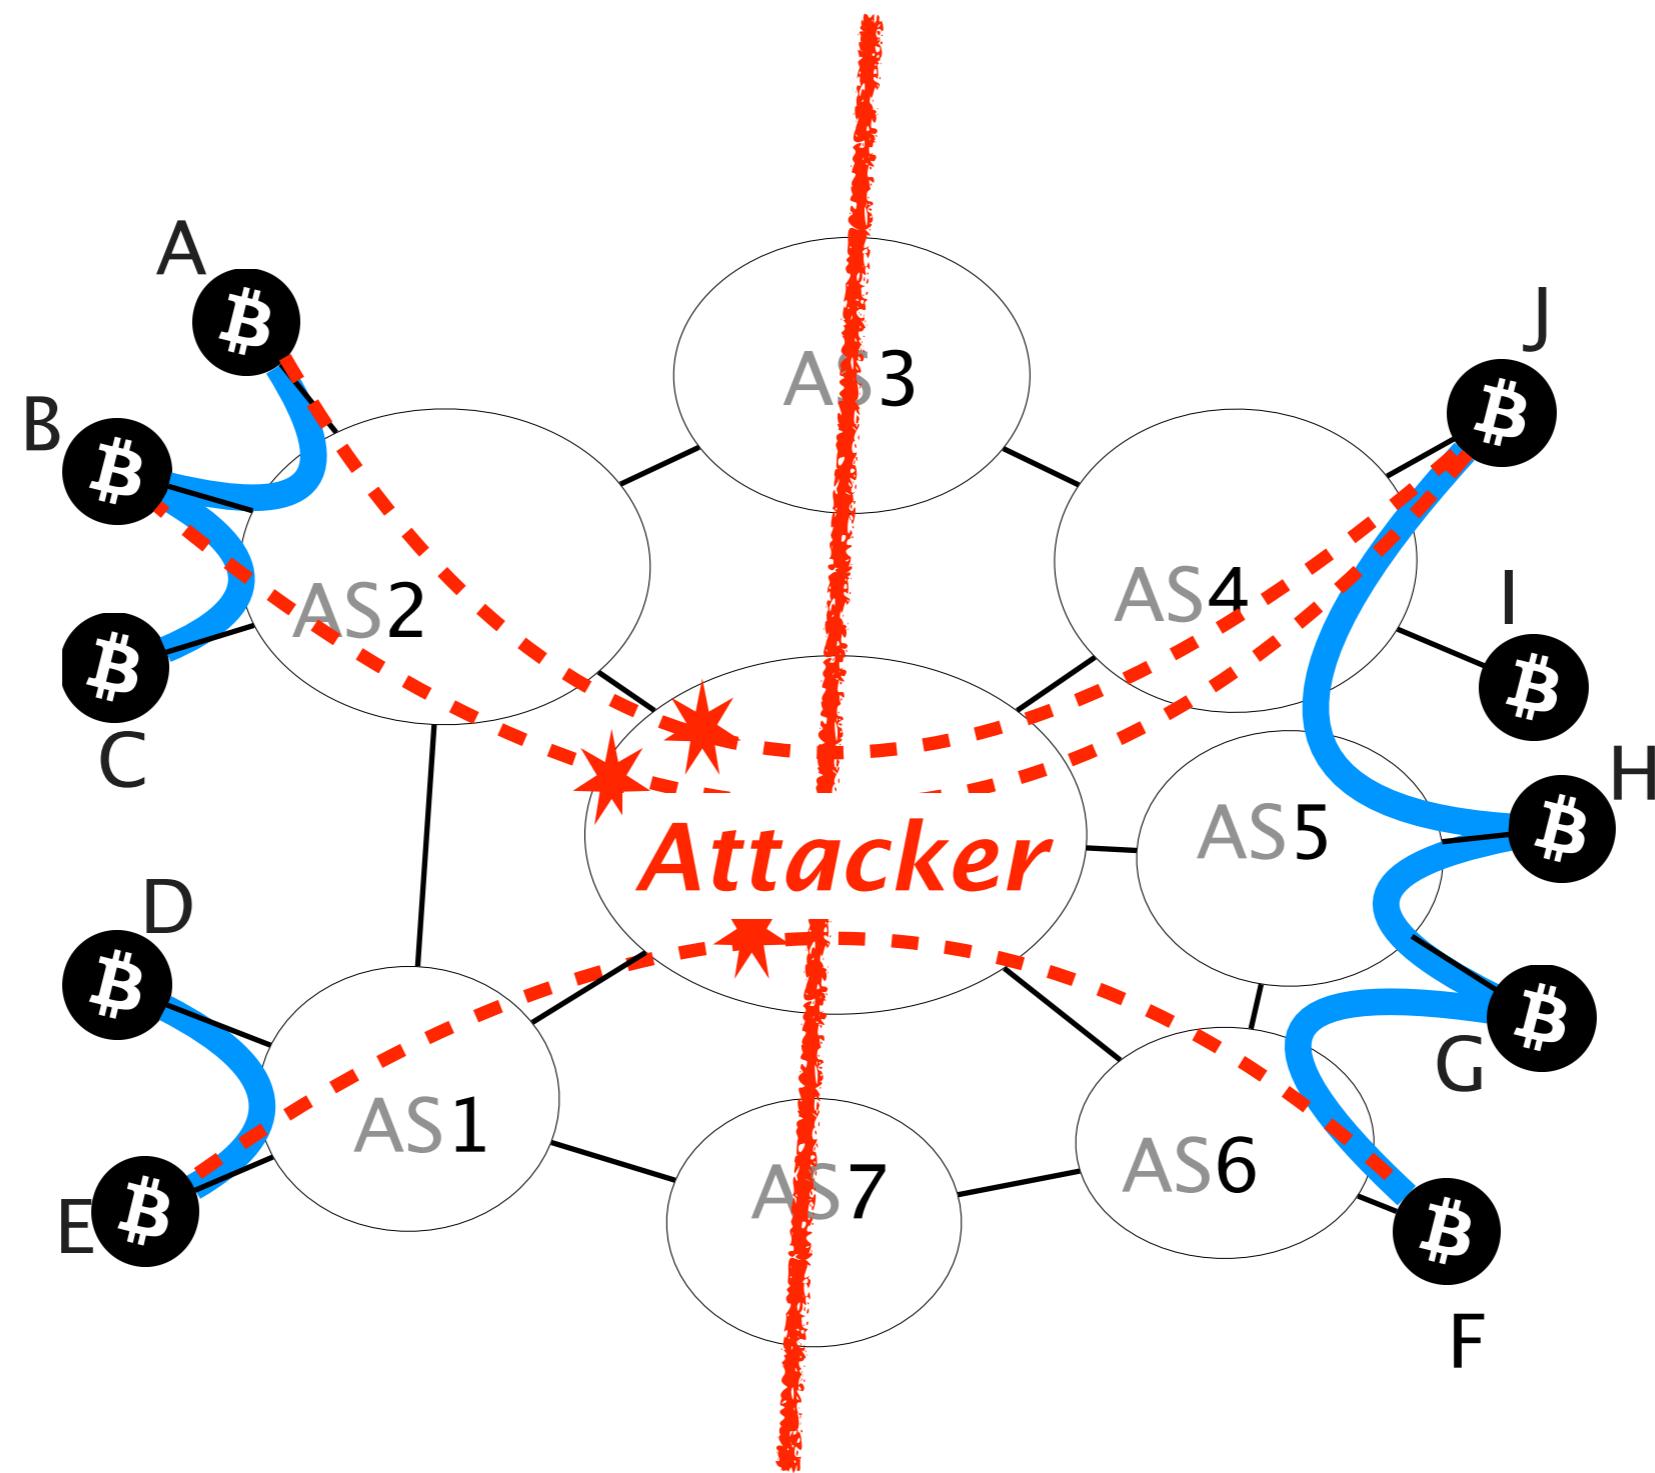

Traffic to node F is **hijacked**

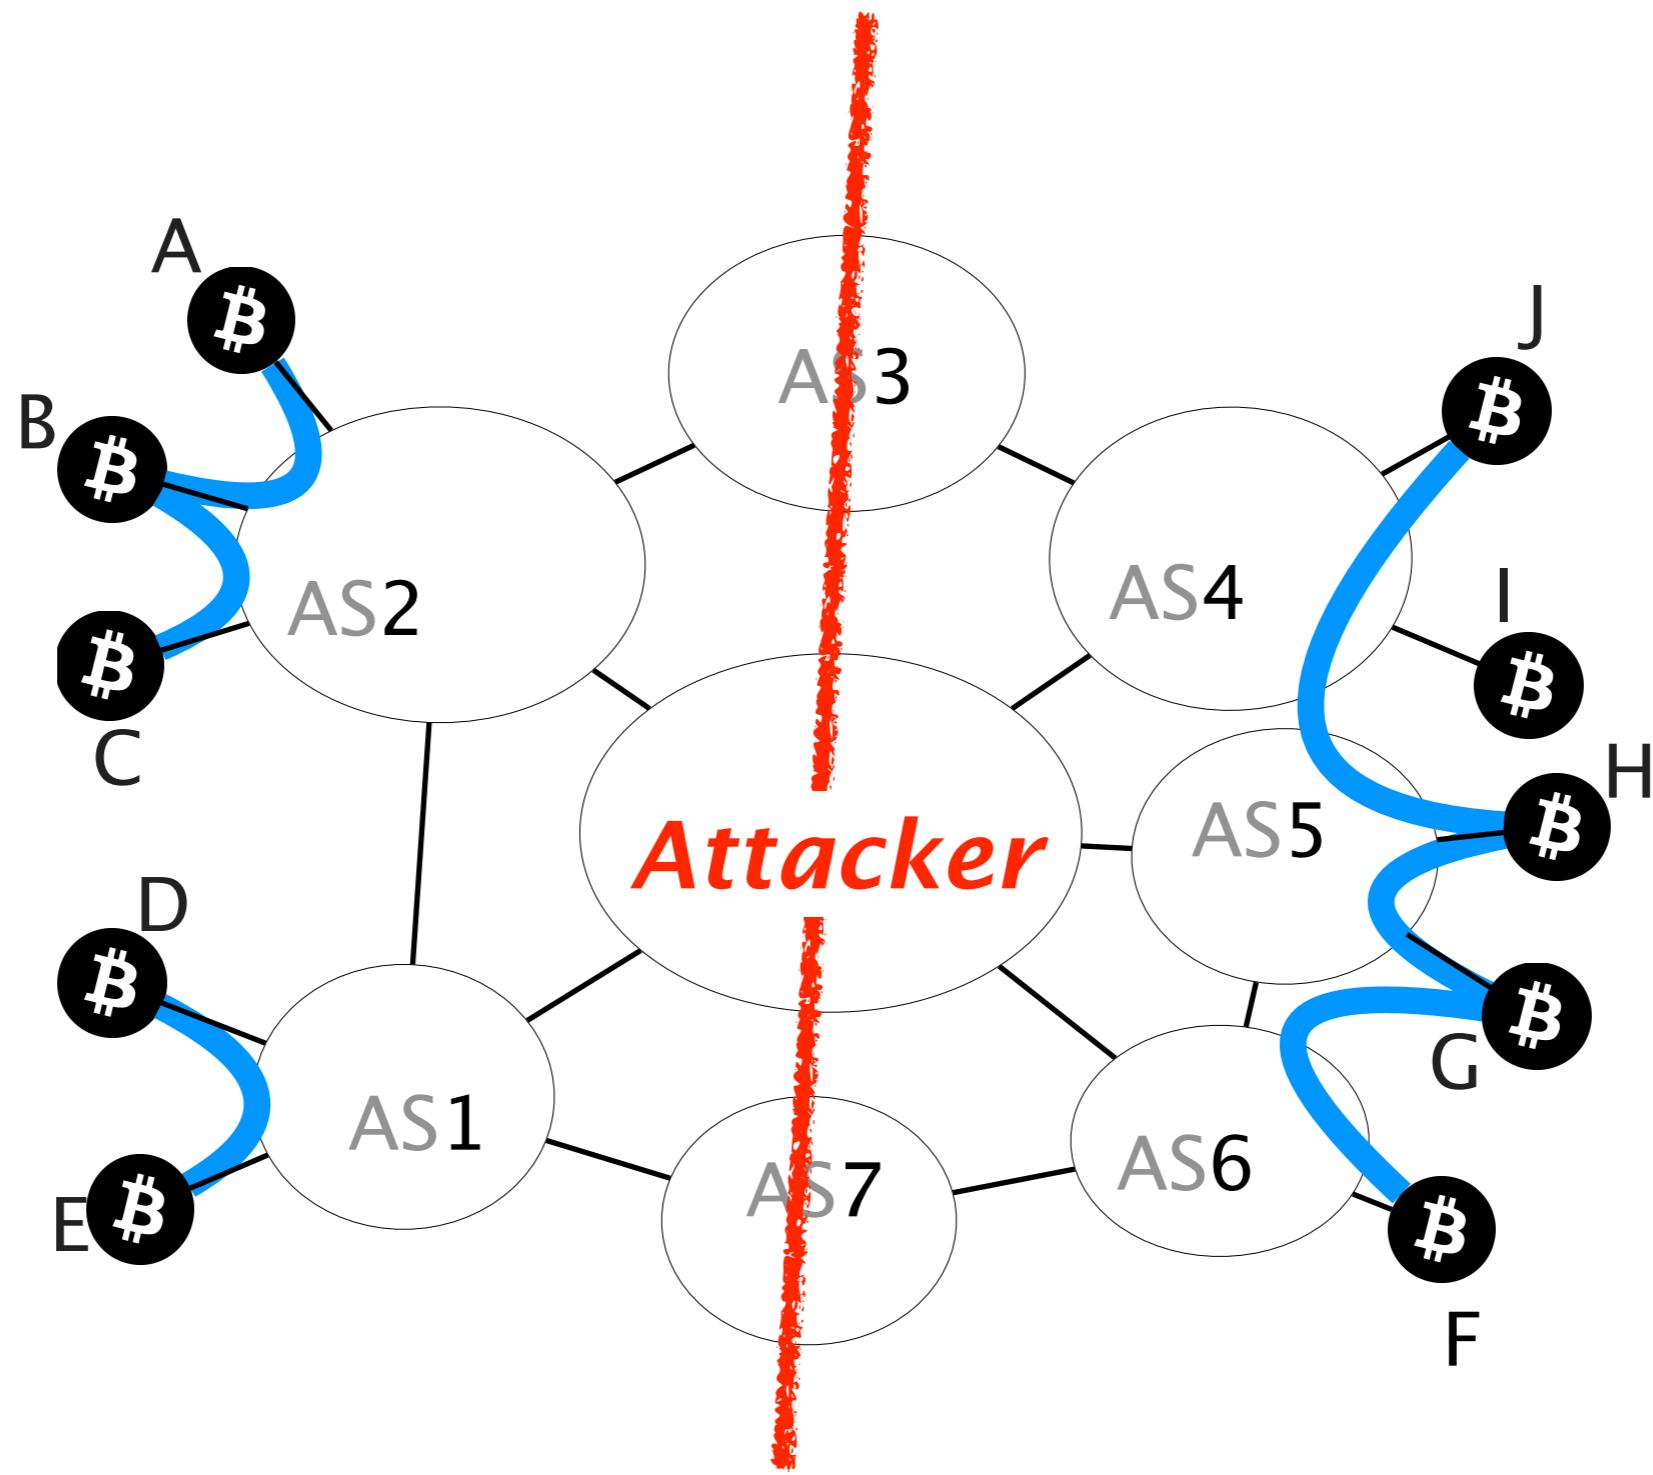

By hijacking the IP prefixes pertaining to the right nodes,  
the attacker can intercept all their connections

Once on-path, the attacker can drop all connections crossing the partition

The partition is created

Not all partition are feasible in practice:  
some connections cannot be intercepted

Bitcoin connections established...

- within a mining pool
- within an AS
- between mining pools with private agreements

cannot be hijacked (usually)

Bitcoin connections established...

- within a mining pool
- within an AS
- between mining pools

cannot be hijacked (usually)

*but* can be *detected* and *located* by the attacker  
enabling her to build a similar but feasible partition

Theorem

Given a set of nodes to disconnect from the network,  
there exist a **unique maximal subset** that can be isolated  
and that the attacker will isolate.

see paper for proof

We evaluated the partition attack in terms of practicality and time efficiency

Practicality

Can it actually happen?

Time efficiency

How long does it take?

We evaluated the partition attack in terms of practicality and time efficiency

Practicality

Time efficiency

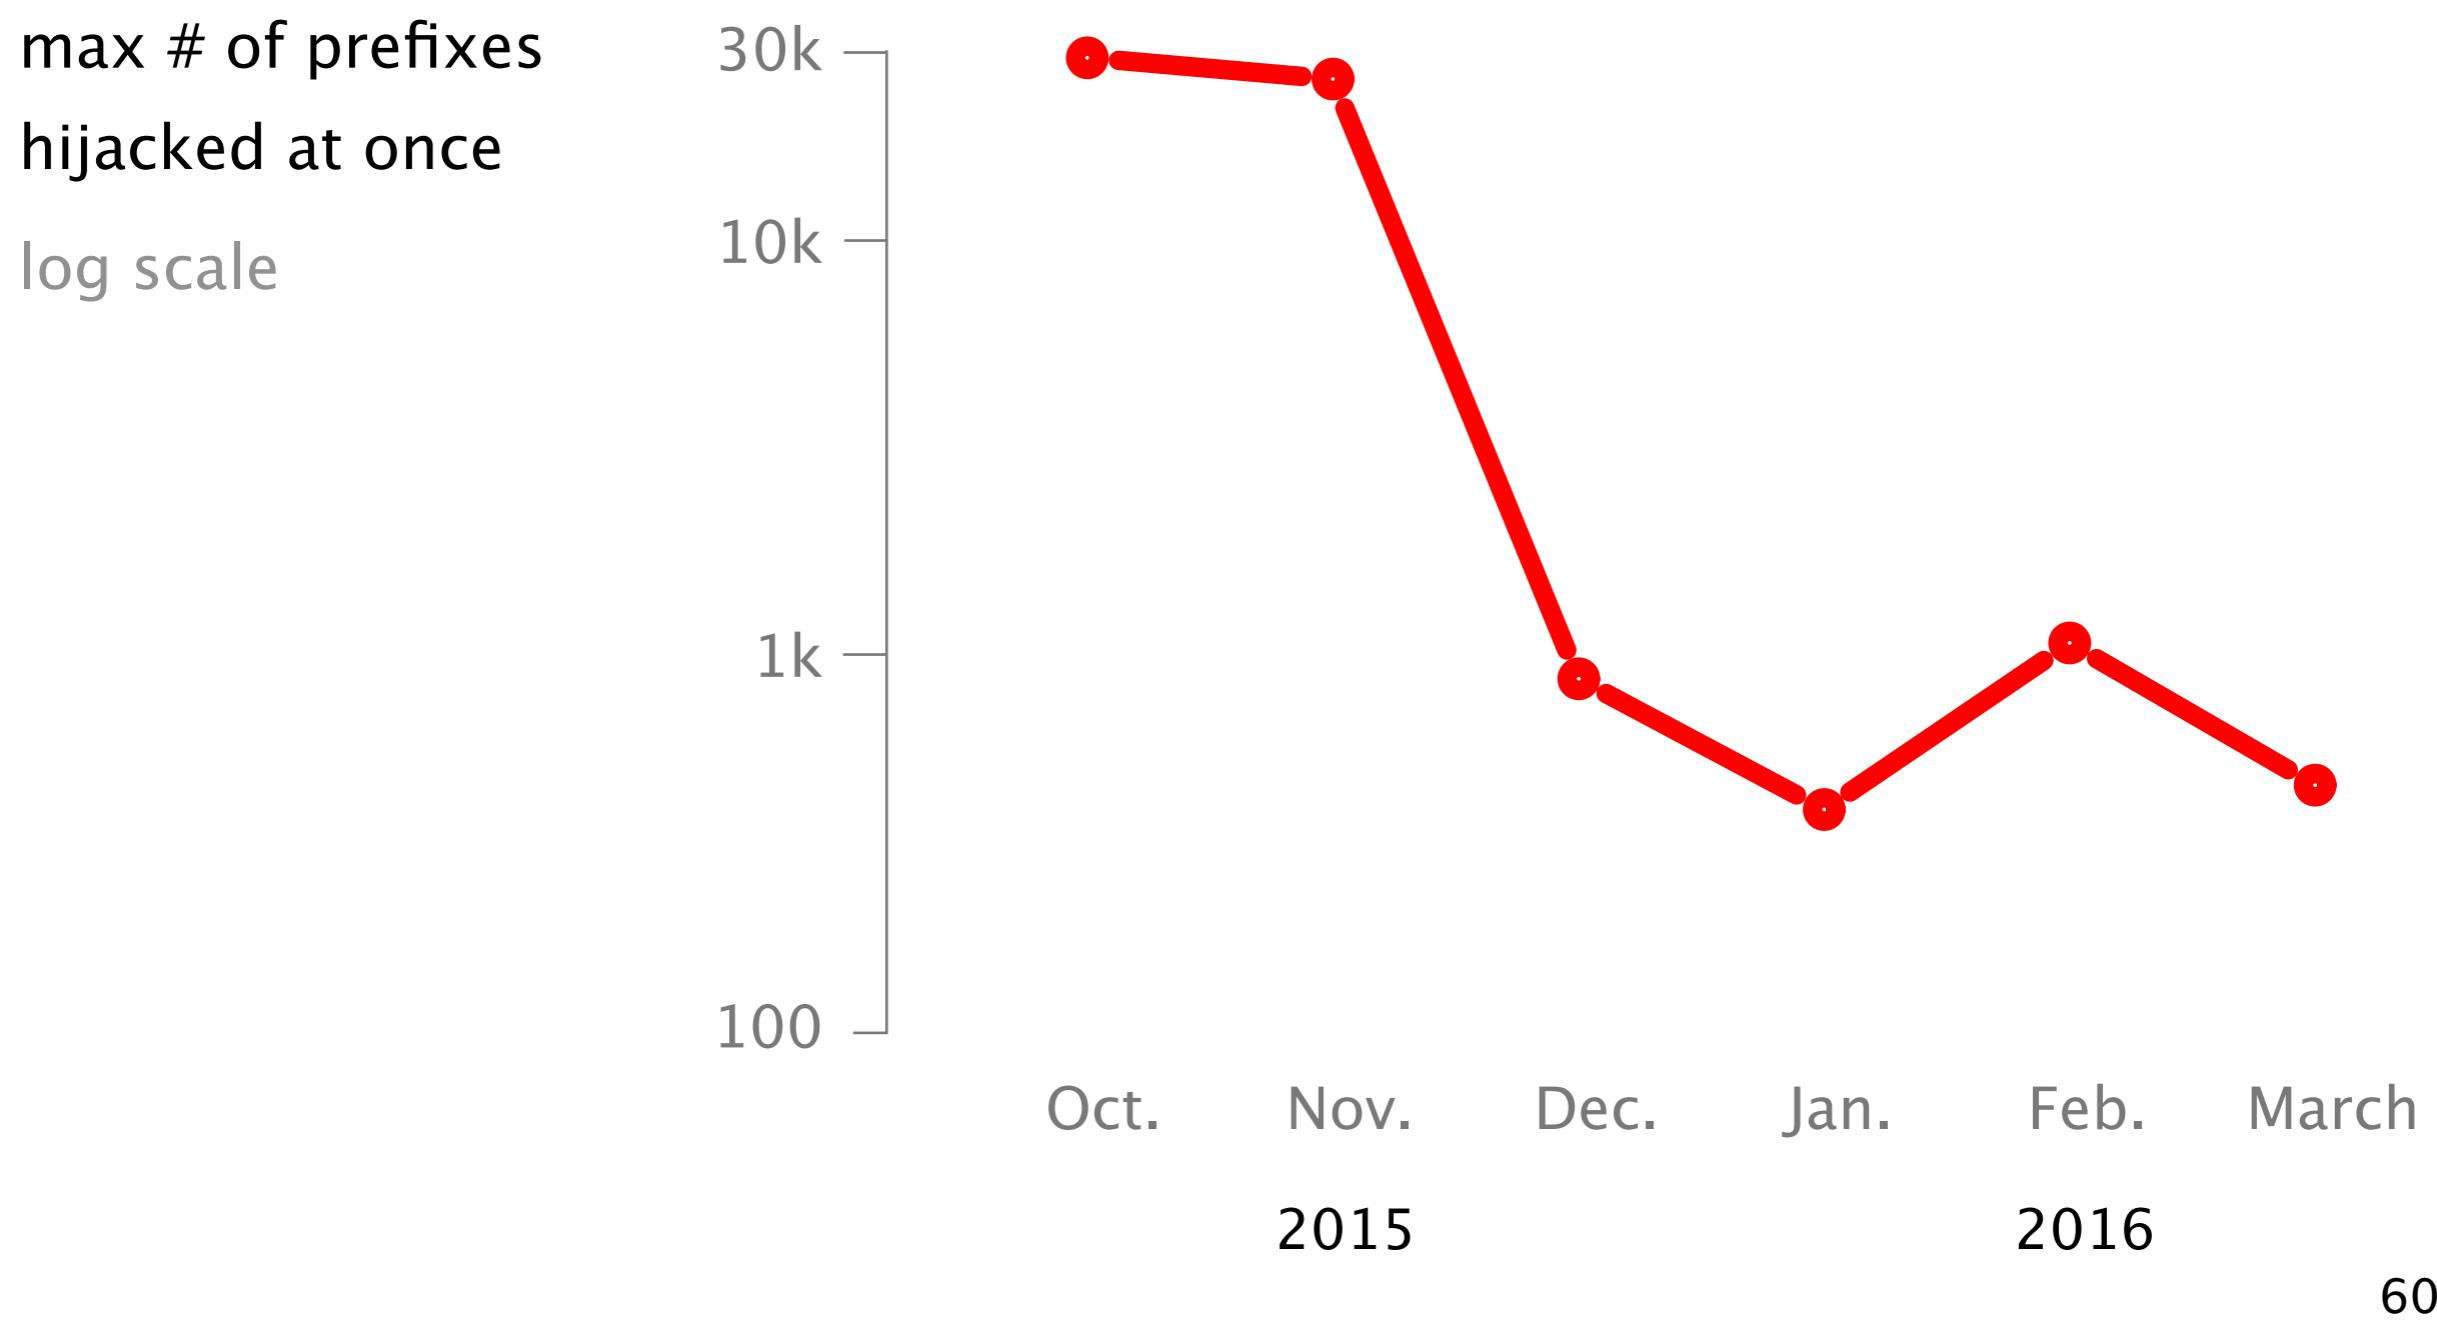

Can it actually happen?

Splitting the mining power **even to half** can be done  
by hijacking **less than 100 prefixes**

Splitting the mining power **even to half** can be done  
by hijacking **less than 100 prefixes**

|  
*negligible* with respect to  
routinely observed hijacks

Hijacks involving up to 1k of prefixes are frequently seen in the Internet today

We also evaluated the partition in terms of time efficiency

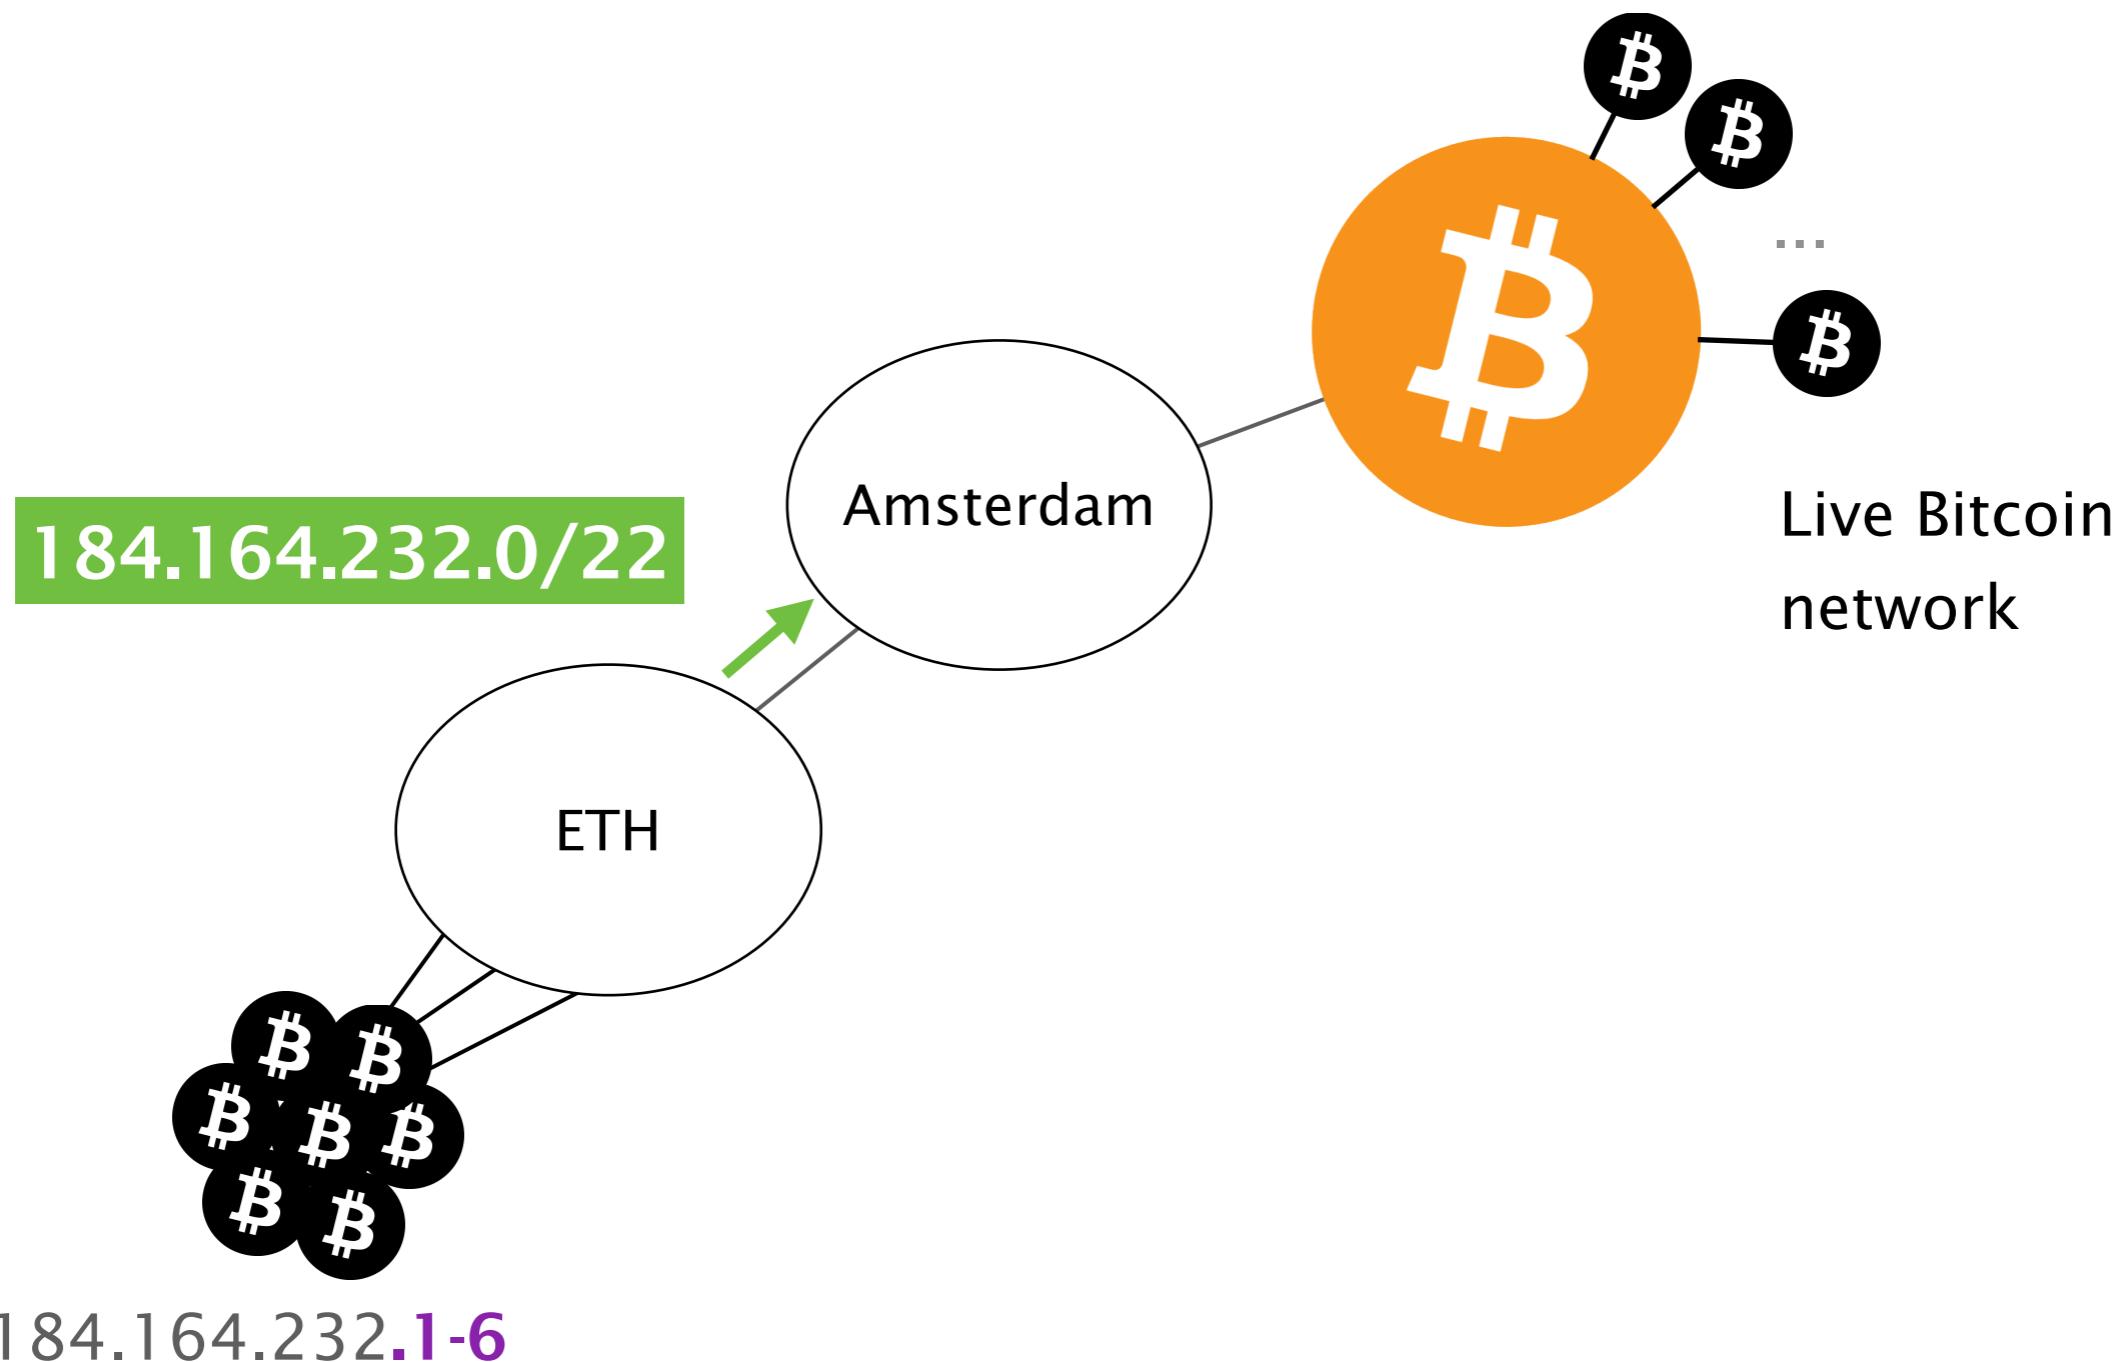

Practicality

Time efficiency

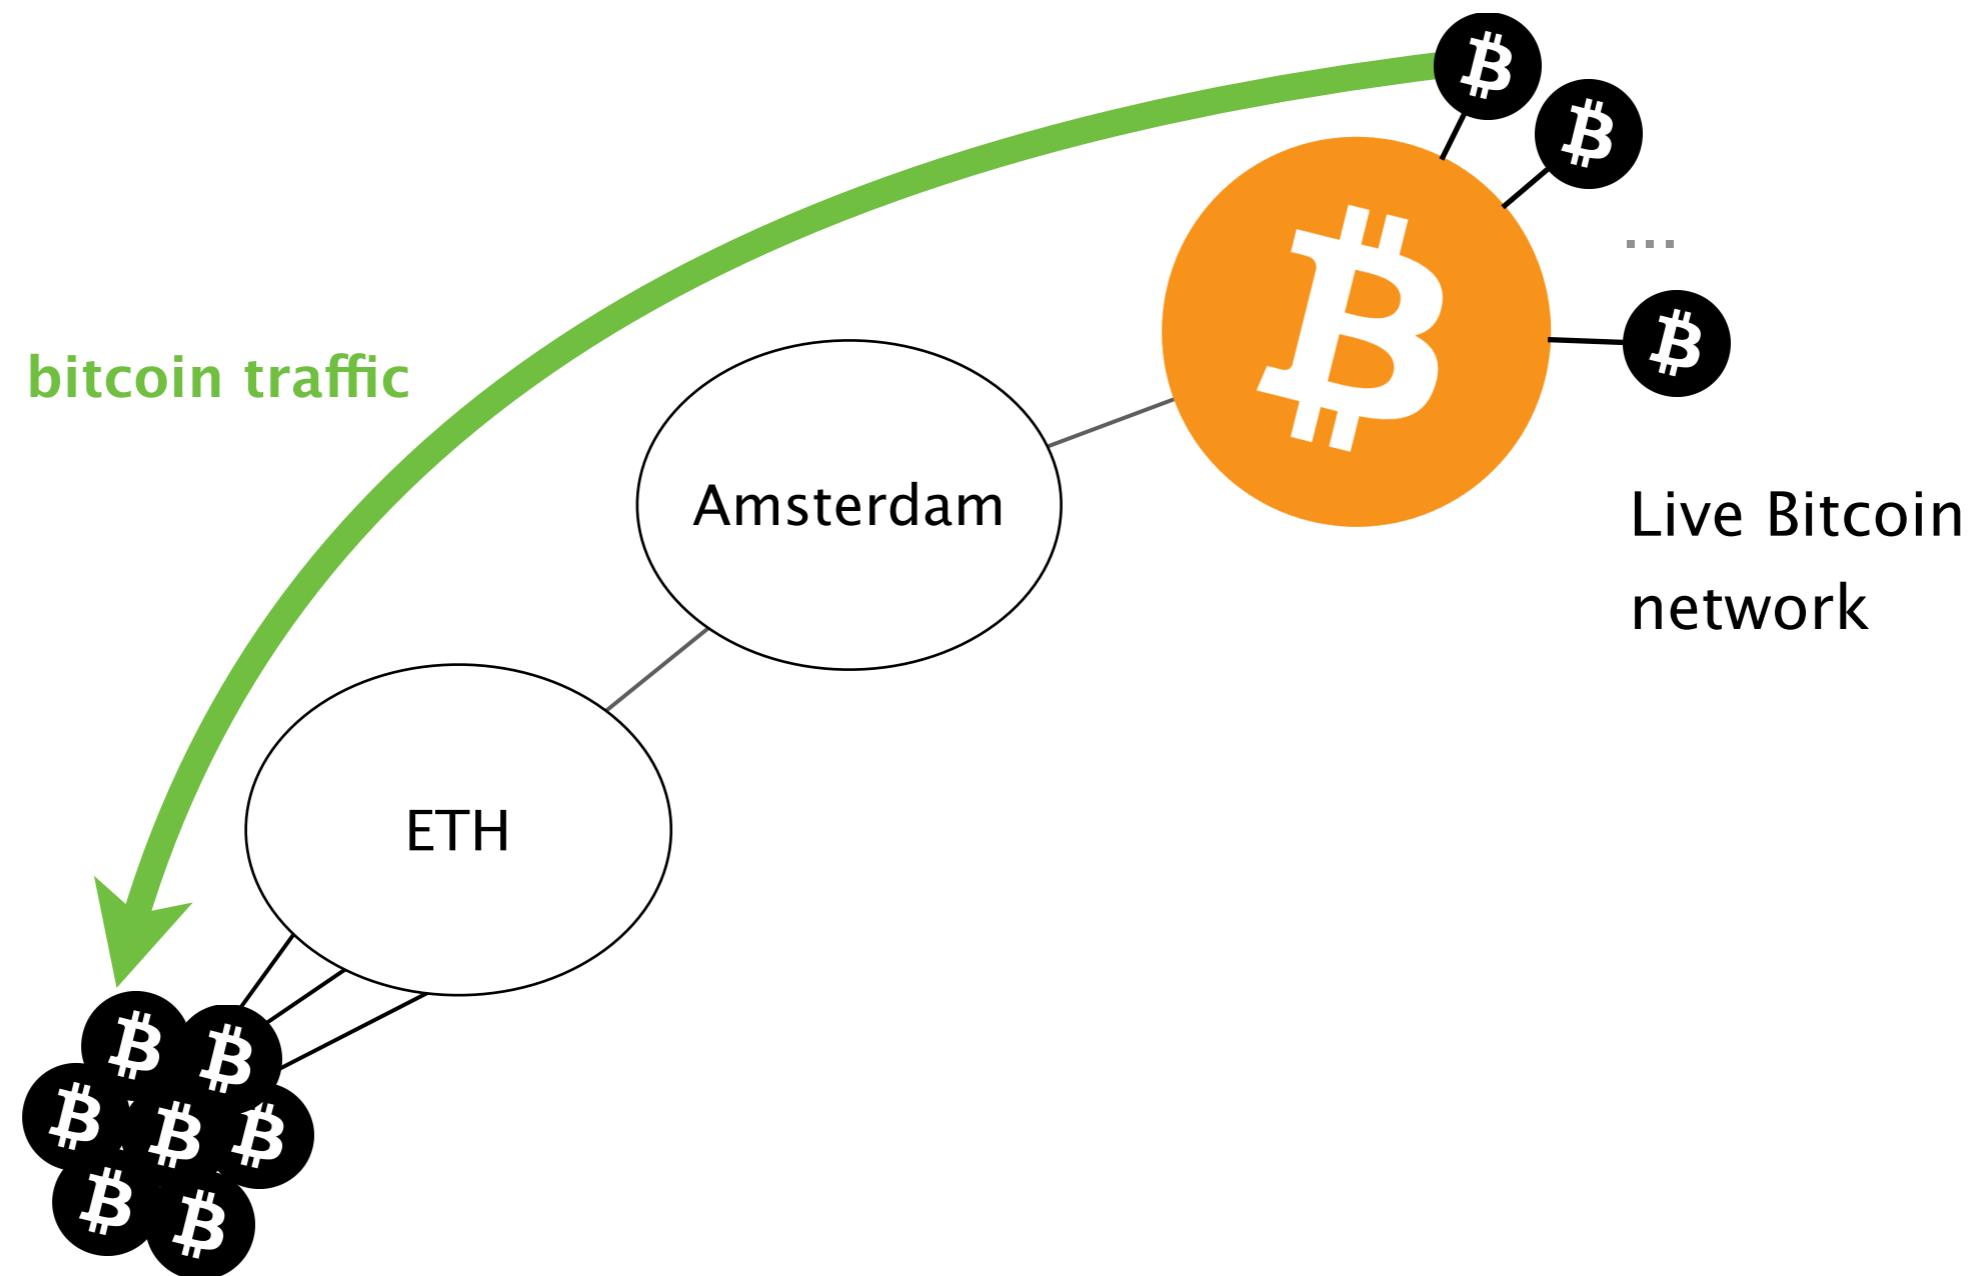

How long does it take?

We measured the time required to perform a partition attack by attacking our own nodes

We hosted a few Bitcoin nodes at ETH and advertised a covering prefix via Amsterdam

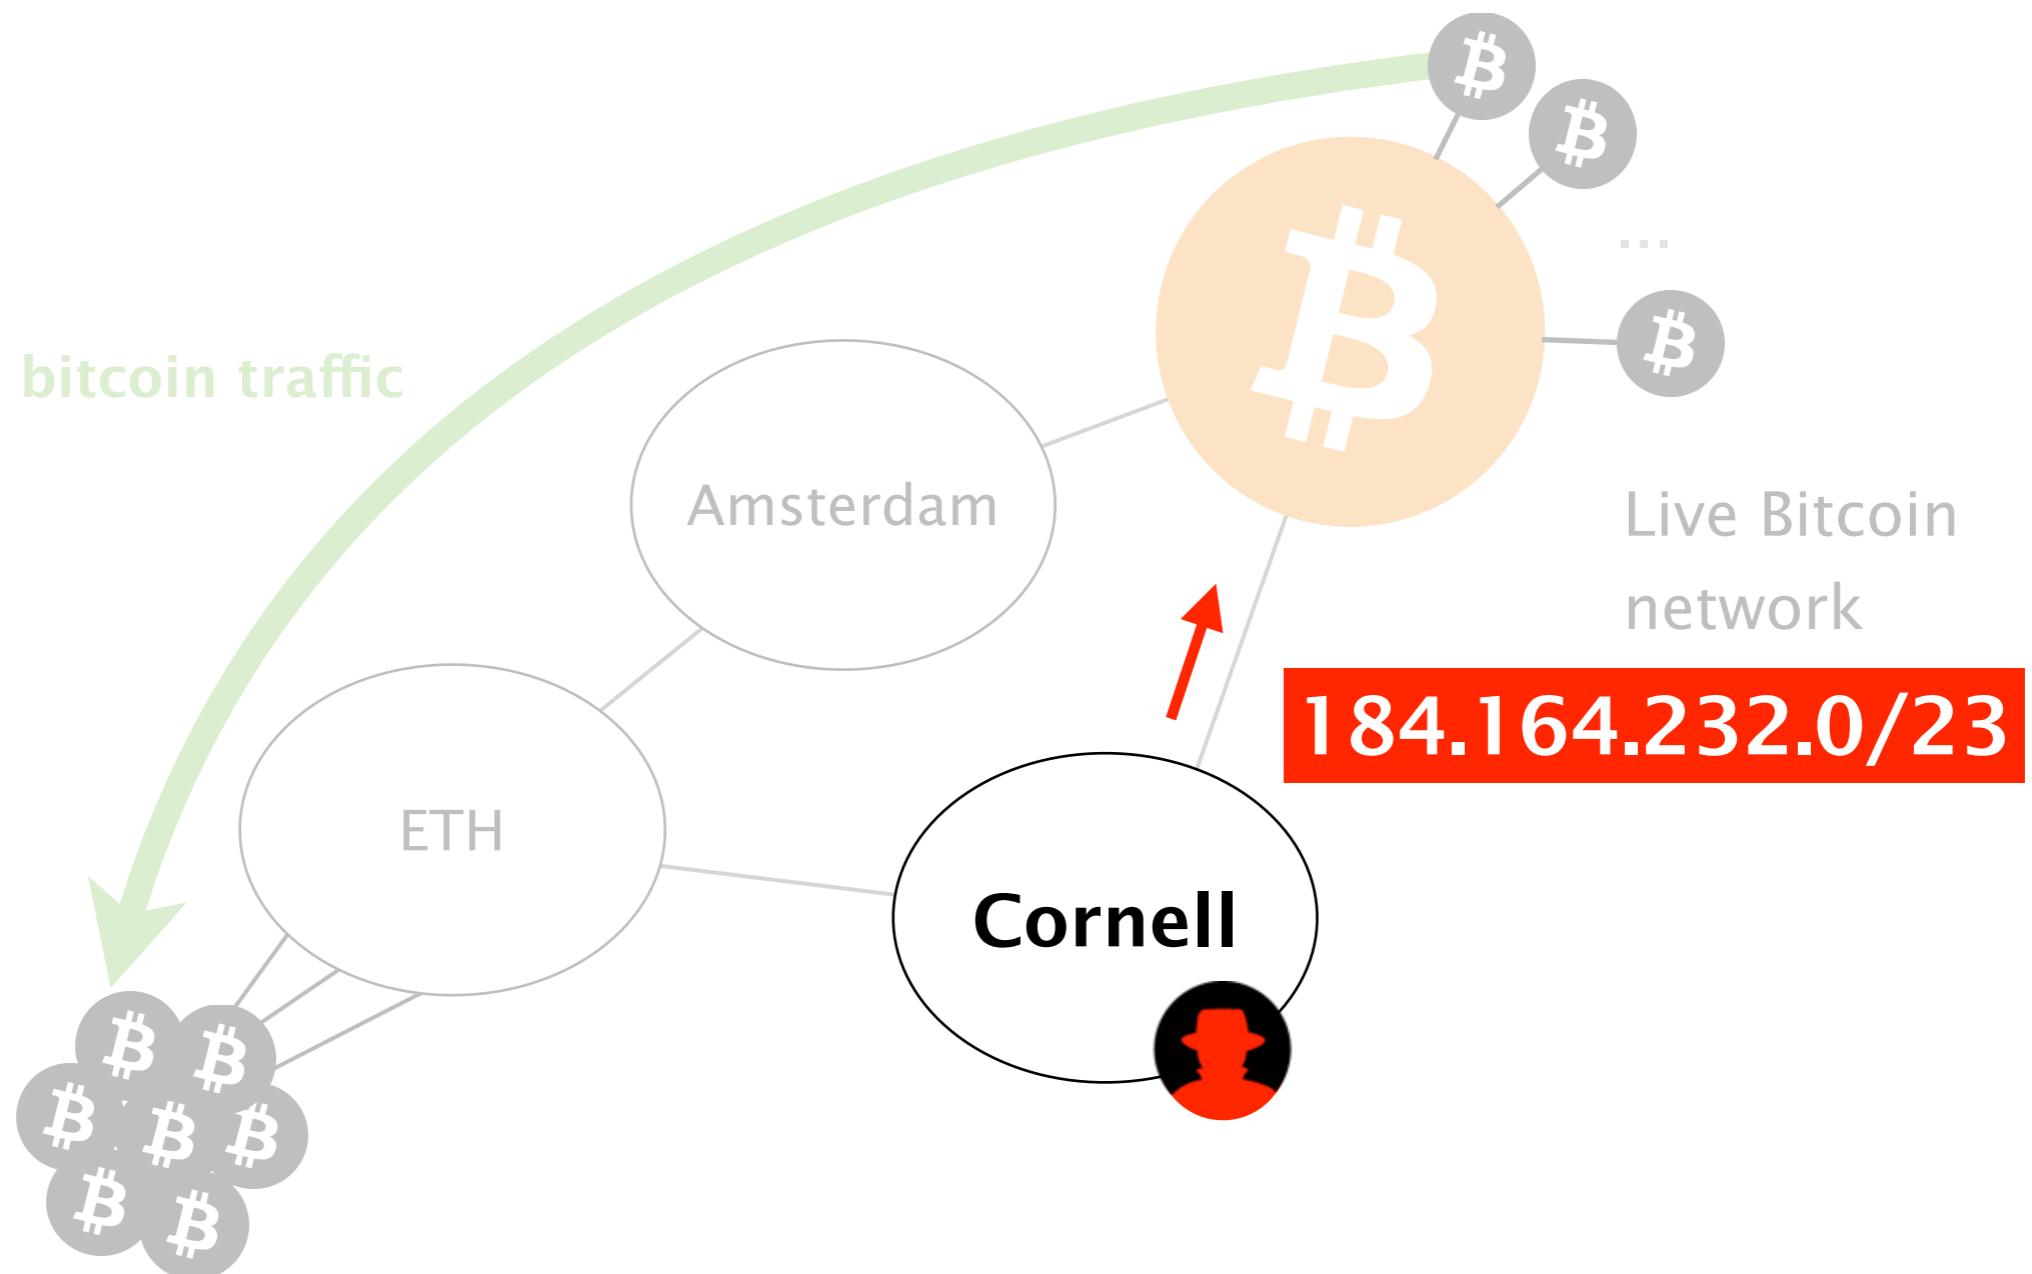

Initially, all the traffic to our nodes  
transits via Amsterdam

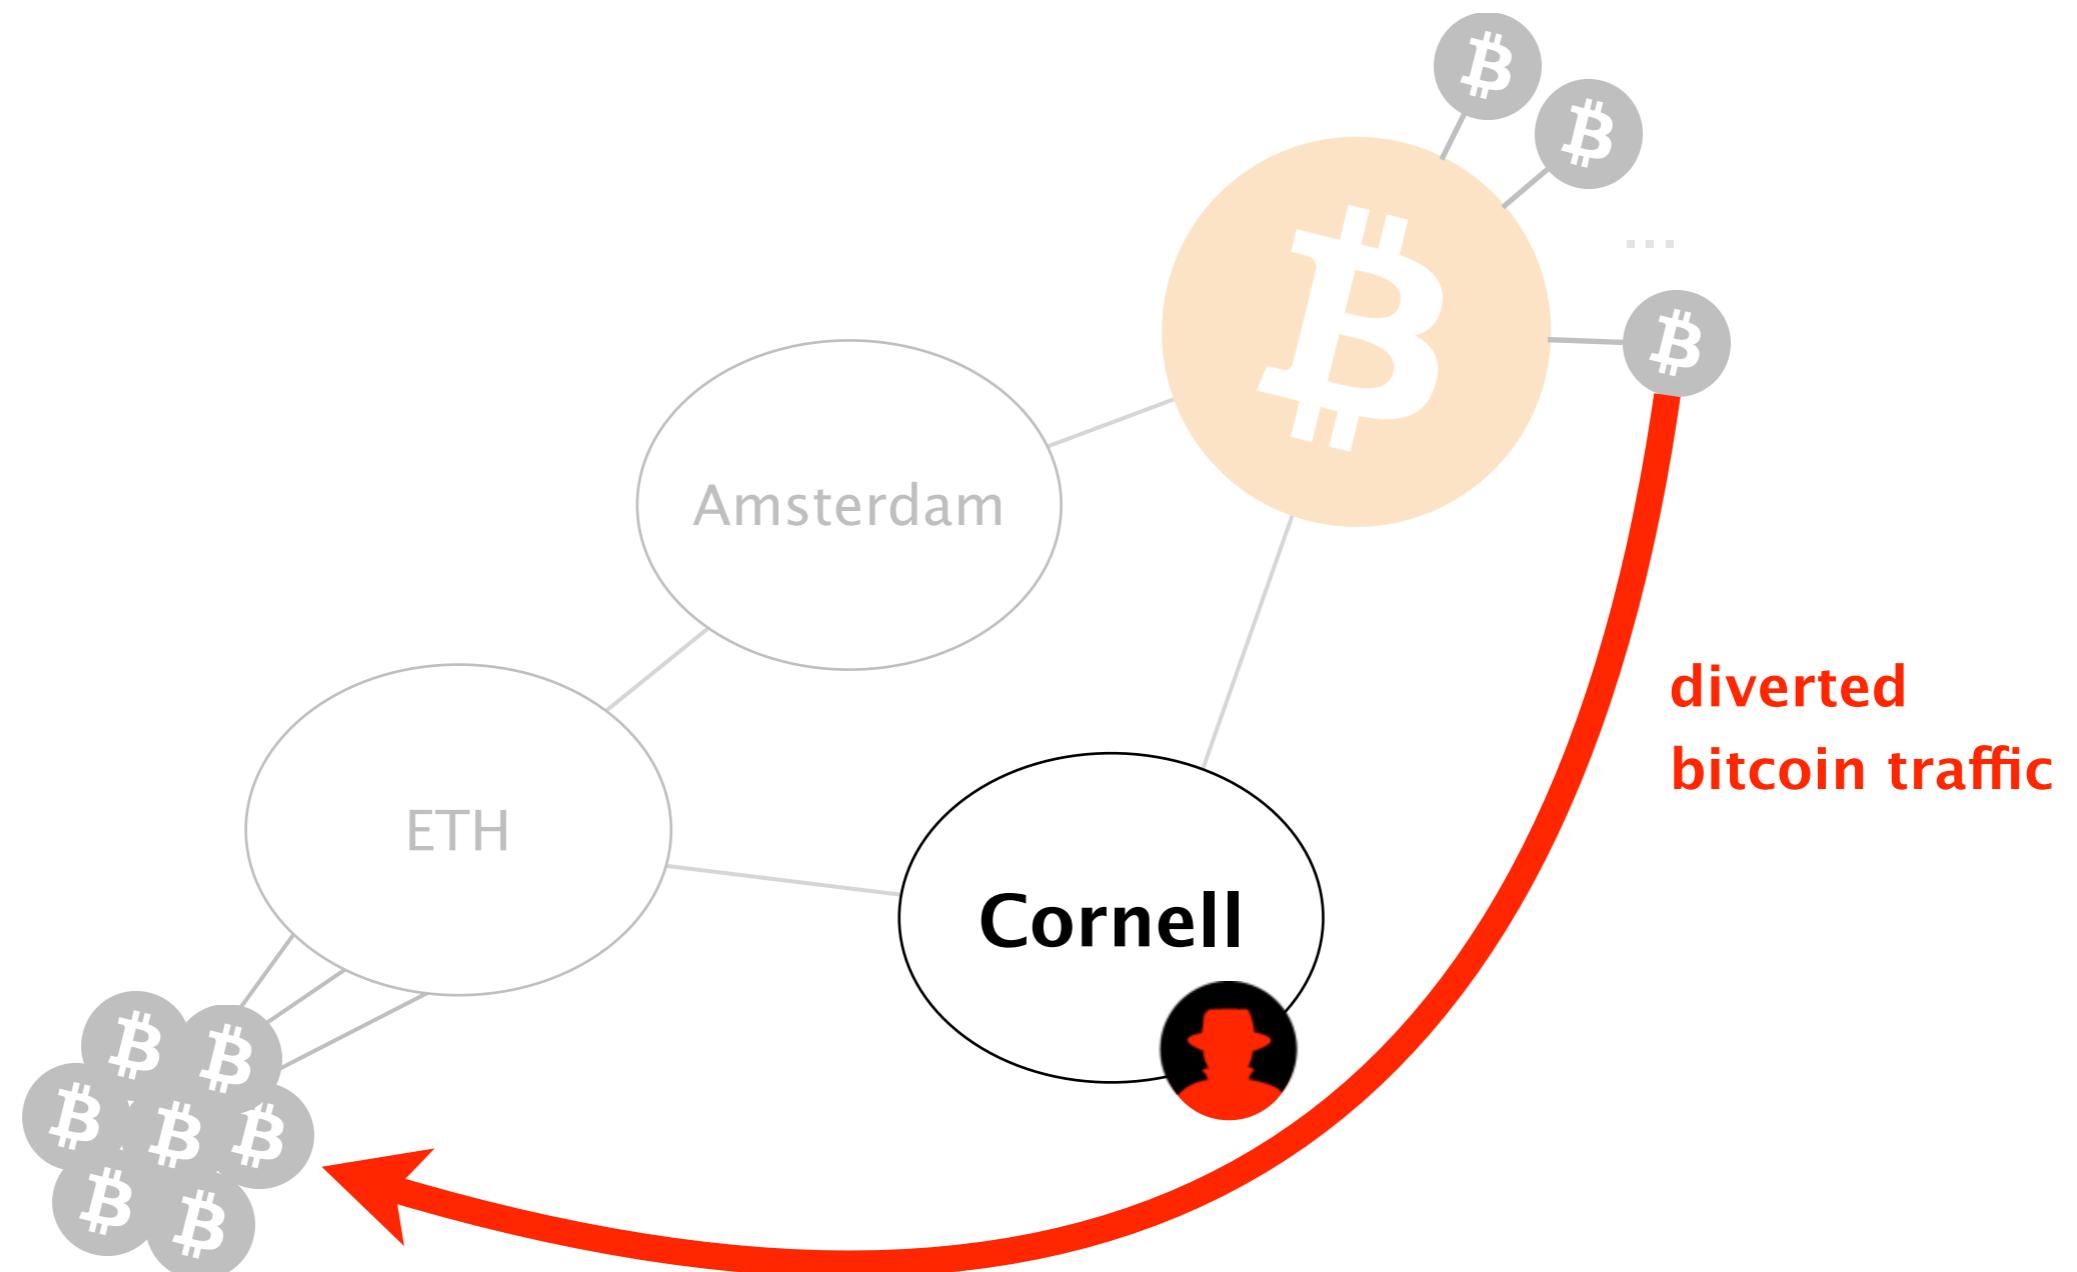

184.164.232.1-6

# We hijacked our nodes

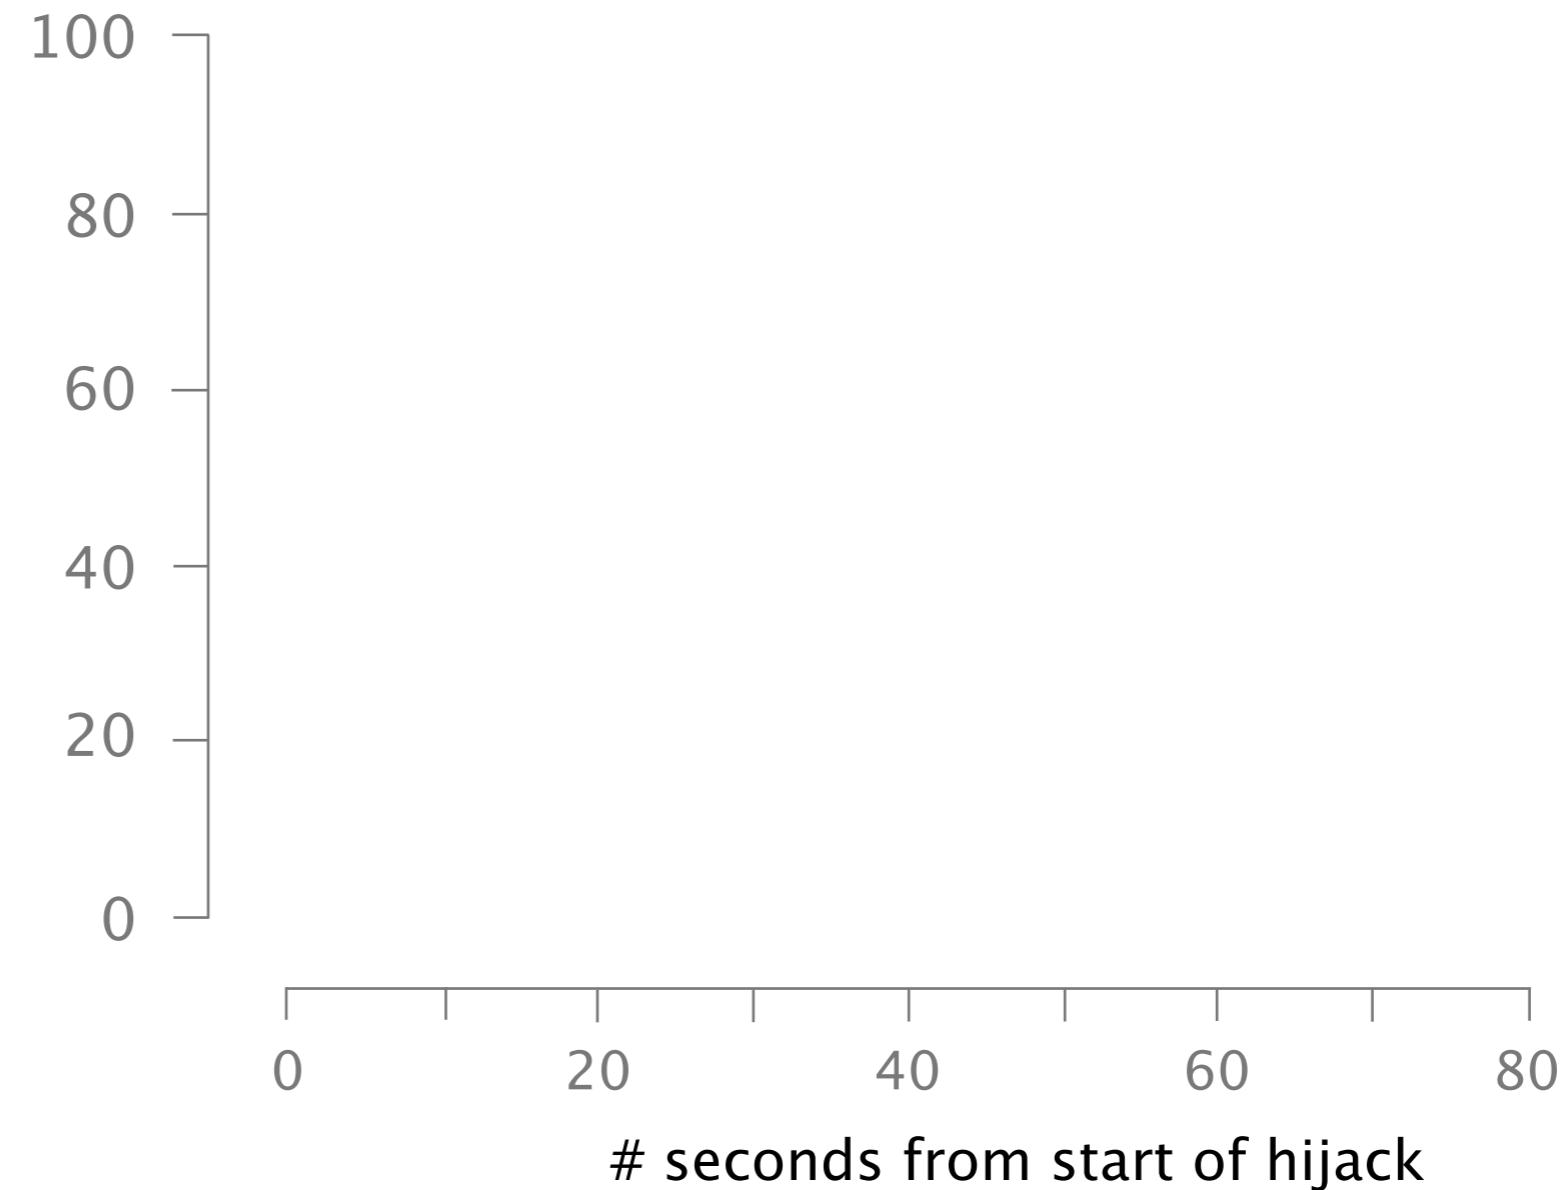

184.164.232.1-6

We measured the time required for a rogue AS to divert all the traffic to our nodes

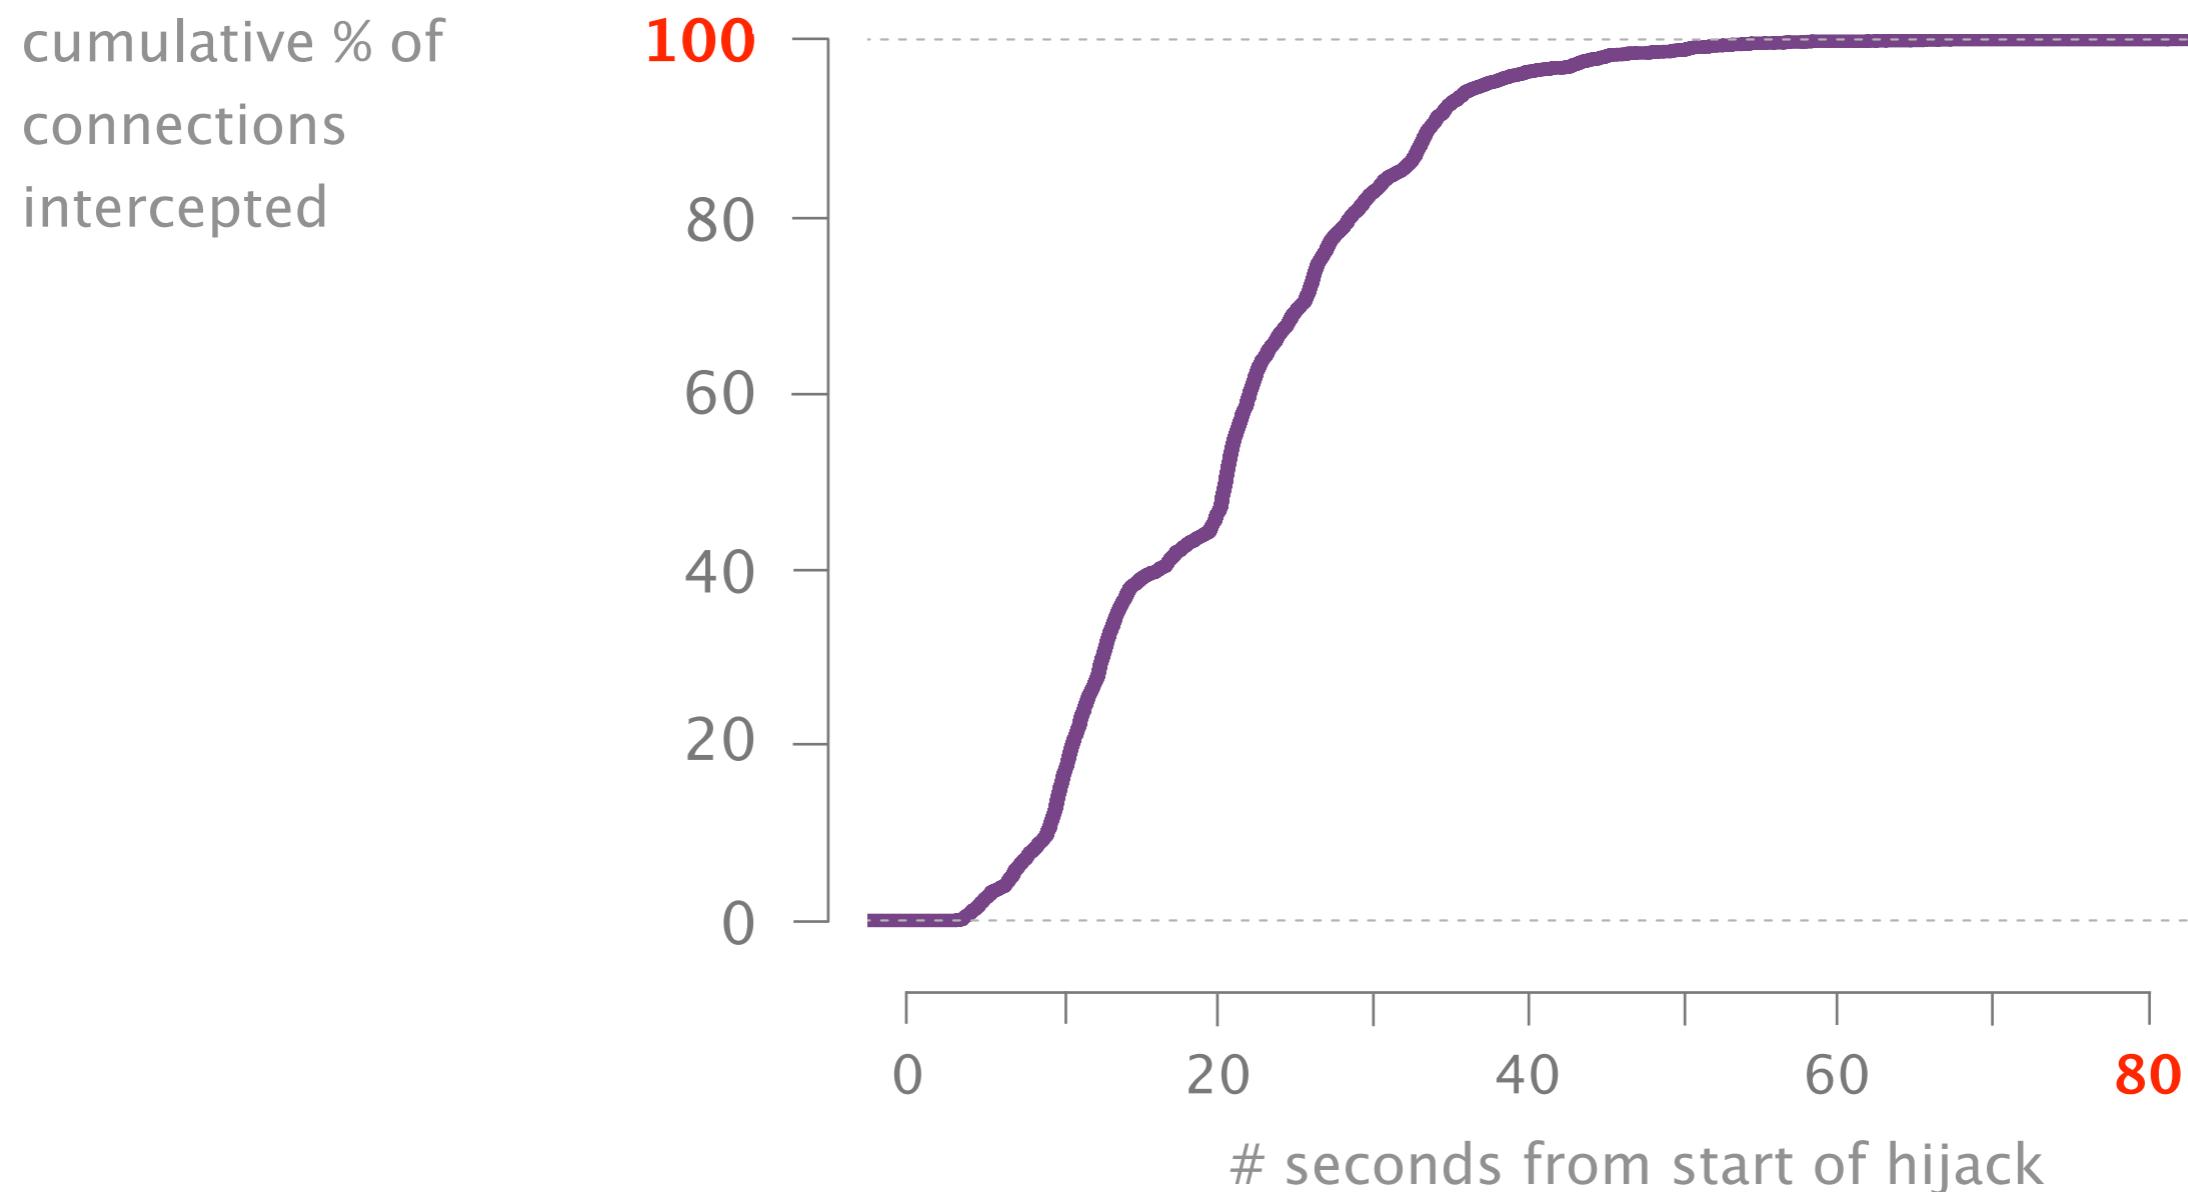

184.164.232.1-6

cumulative % of  
connections  
intercepted

It takes less than 2 minutes for the attacker  
to intercept all the connections

Mitigating a hijack is a human-driven process,  
as such it often takes hours to be resolved

Mitigating a hijack is a human–driven process,  
as such it often takes **hours** to be resolved

|  
It took **Google** close to 3h  
to mitigate a large hijack in 2008 [6]  
(same hold for more recent hijacks)

# Hijacking Bitcoin

## Routing Attacks on Cryptocurrencies

- 1 **Background**  
BGP & Bitcoin
- 2 **Partitioning attack**  
splitting the network
- 3 **Delay attack**  
slowing the network down
- 4 **Countermeasures**  
short-term & long-term

The goal of a **delay** attack is to keep the victim uninformed of the latest Block

The impact of delay attacks is worrying  
and depends on the victim

Merchant

Mining pool

Regular node

The impact of delay attacks is worrying  
and depends on the victim

Merchant

Mining pool

Regular node

susceptible to be the victim  
of double-spending attacks

The impact of delay attacks is worrying  
and depends on the victim

Merchant

Mining pool

Regular node

waste their mining power by  
mining on an obsolete chain

The impact of delay attacks is worrying  
and depends on the victim

Merchant

Mining pool

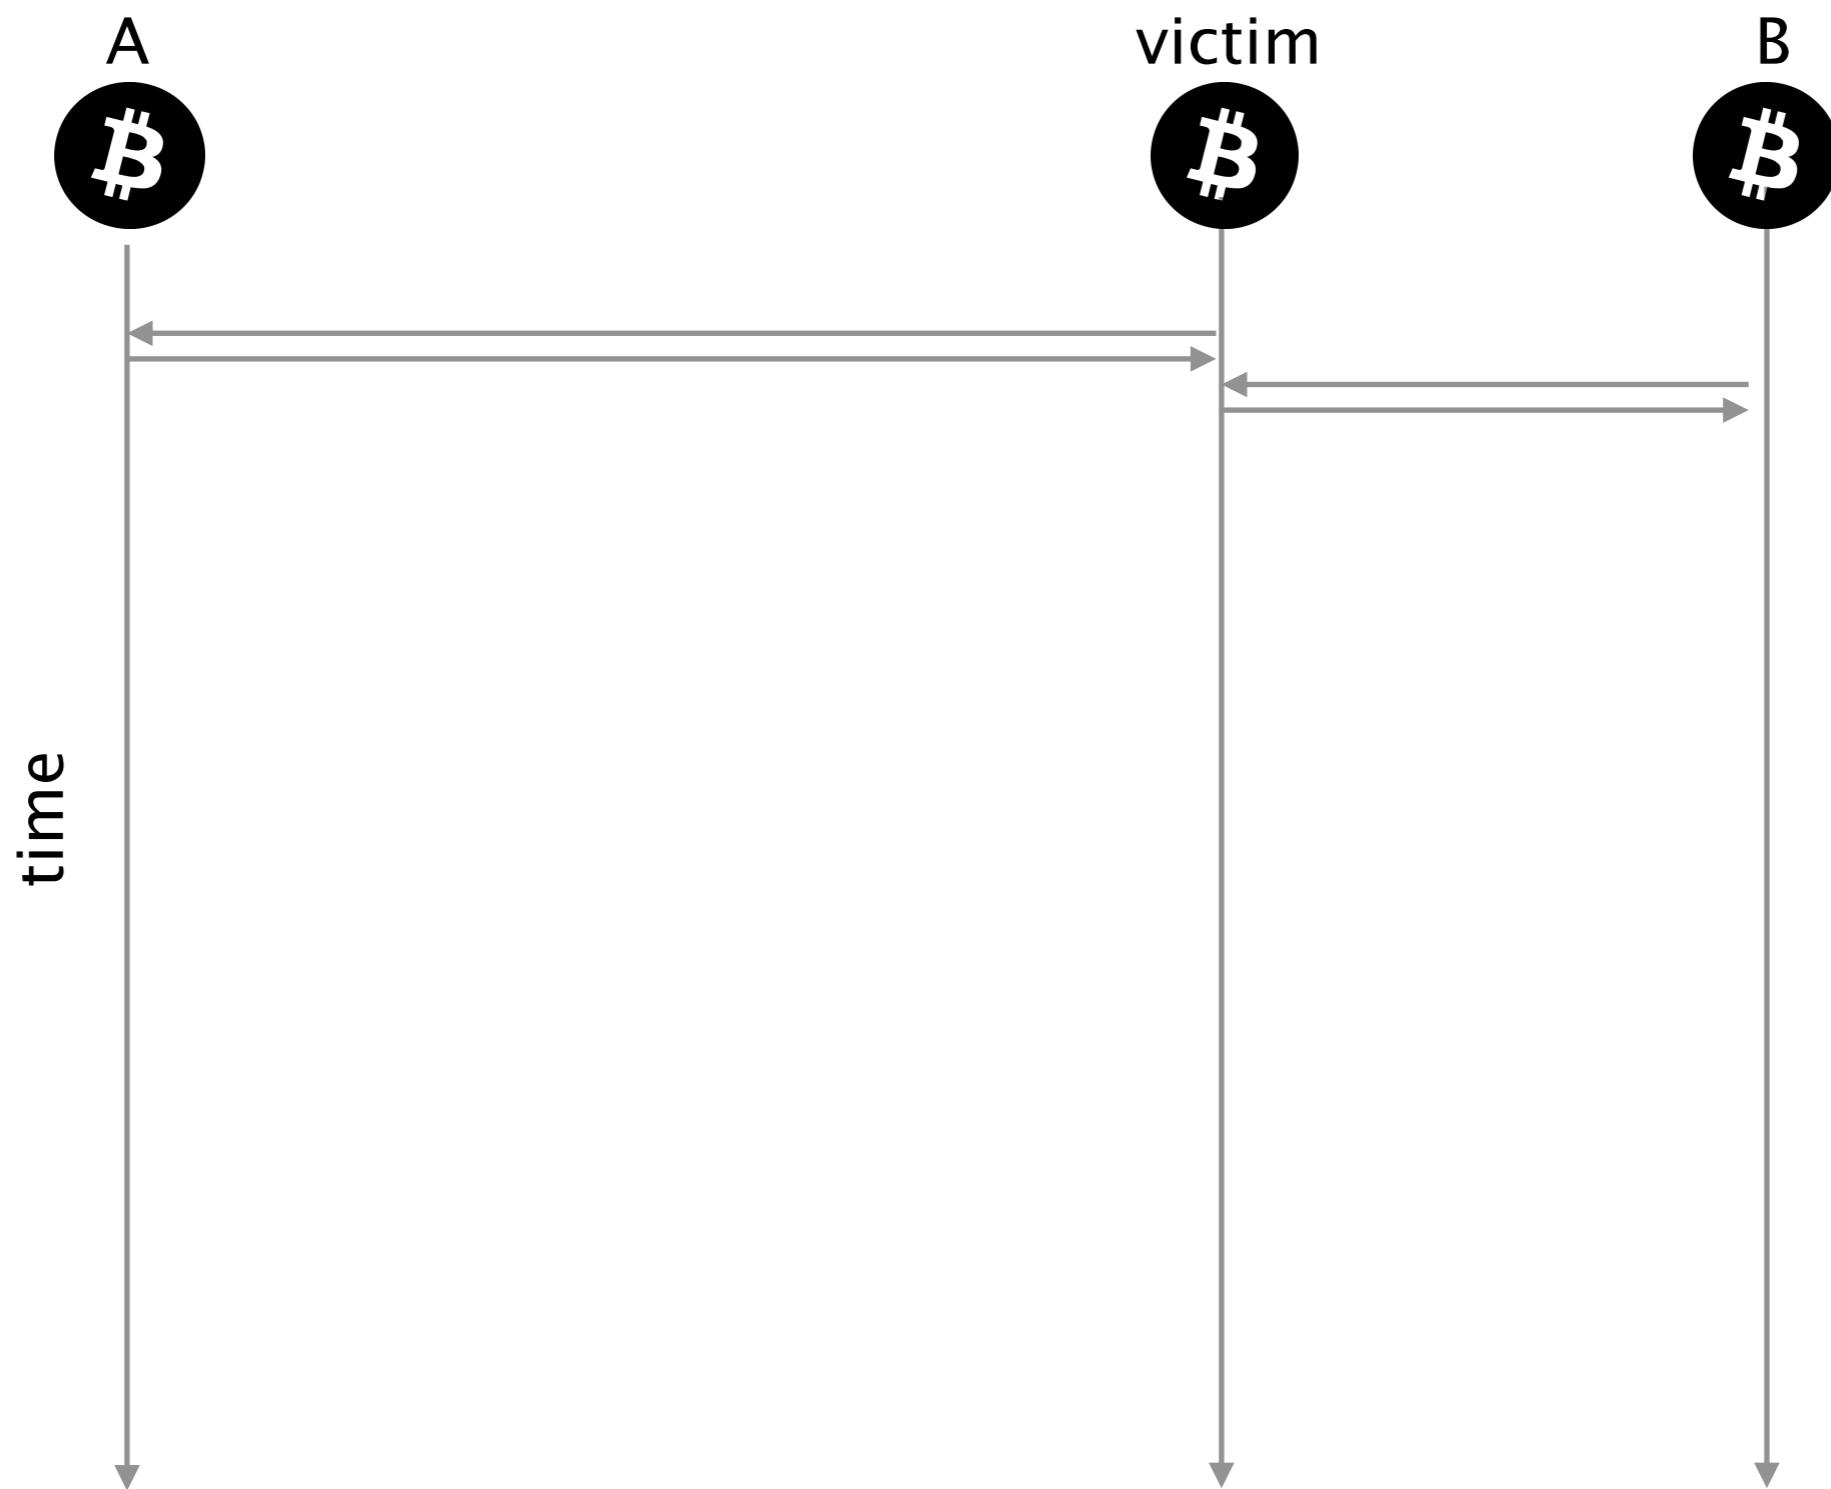

Regular node

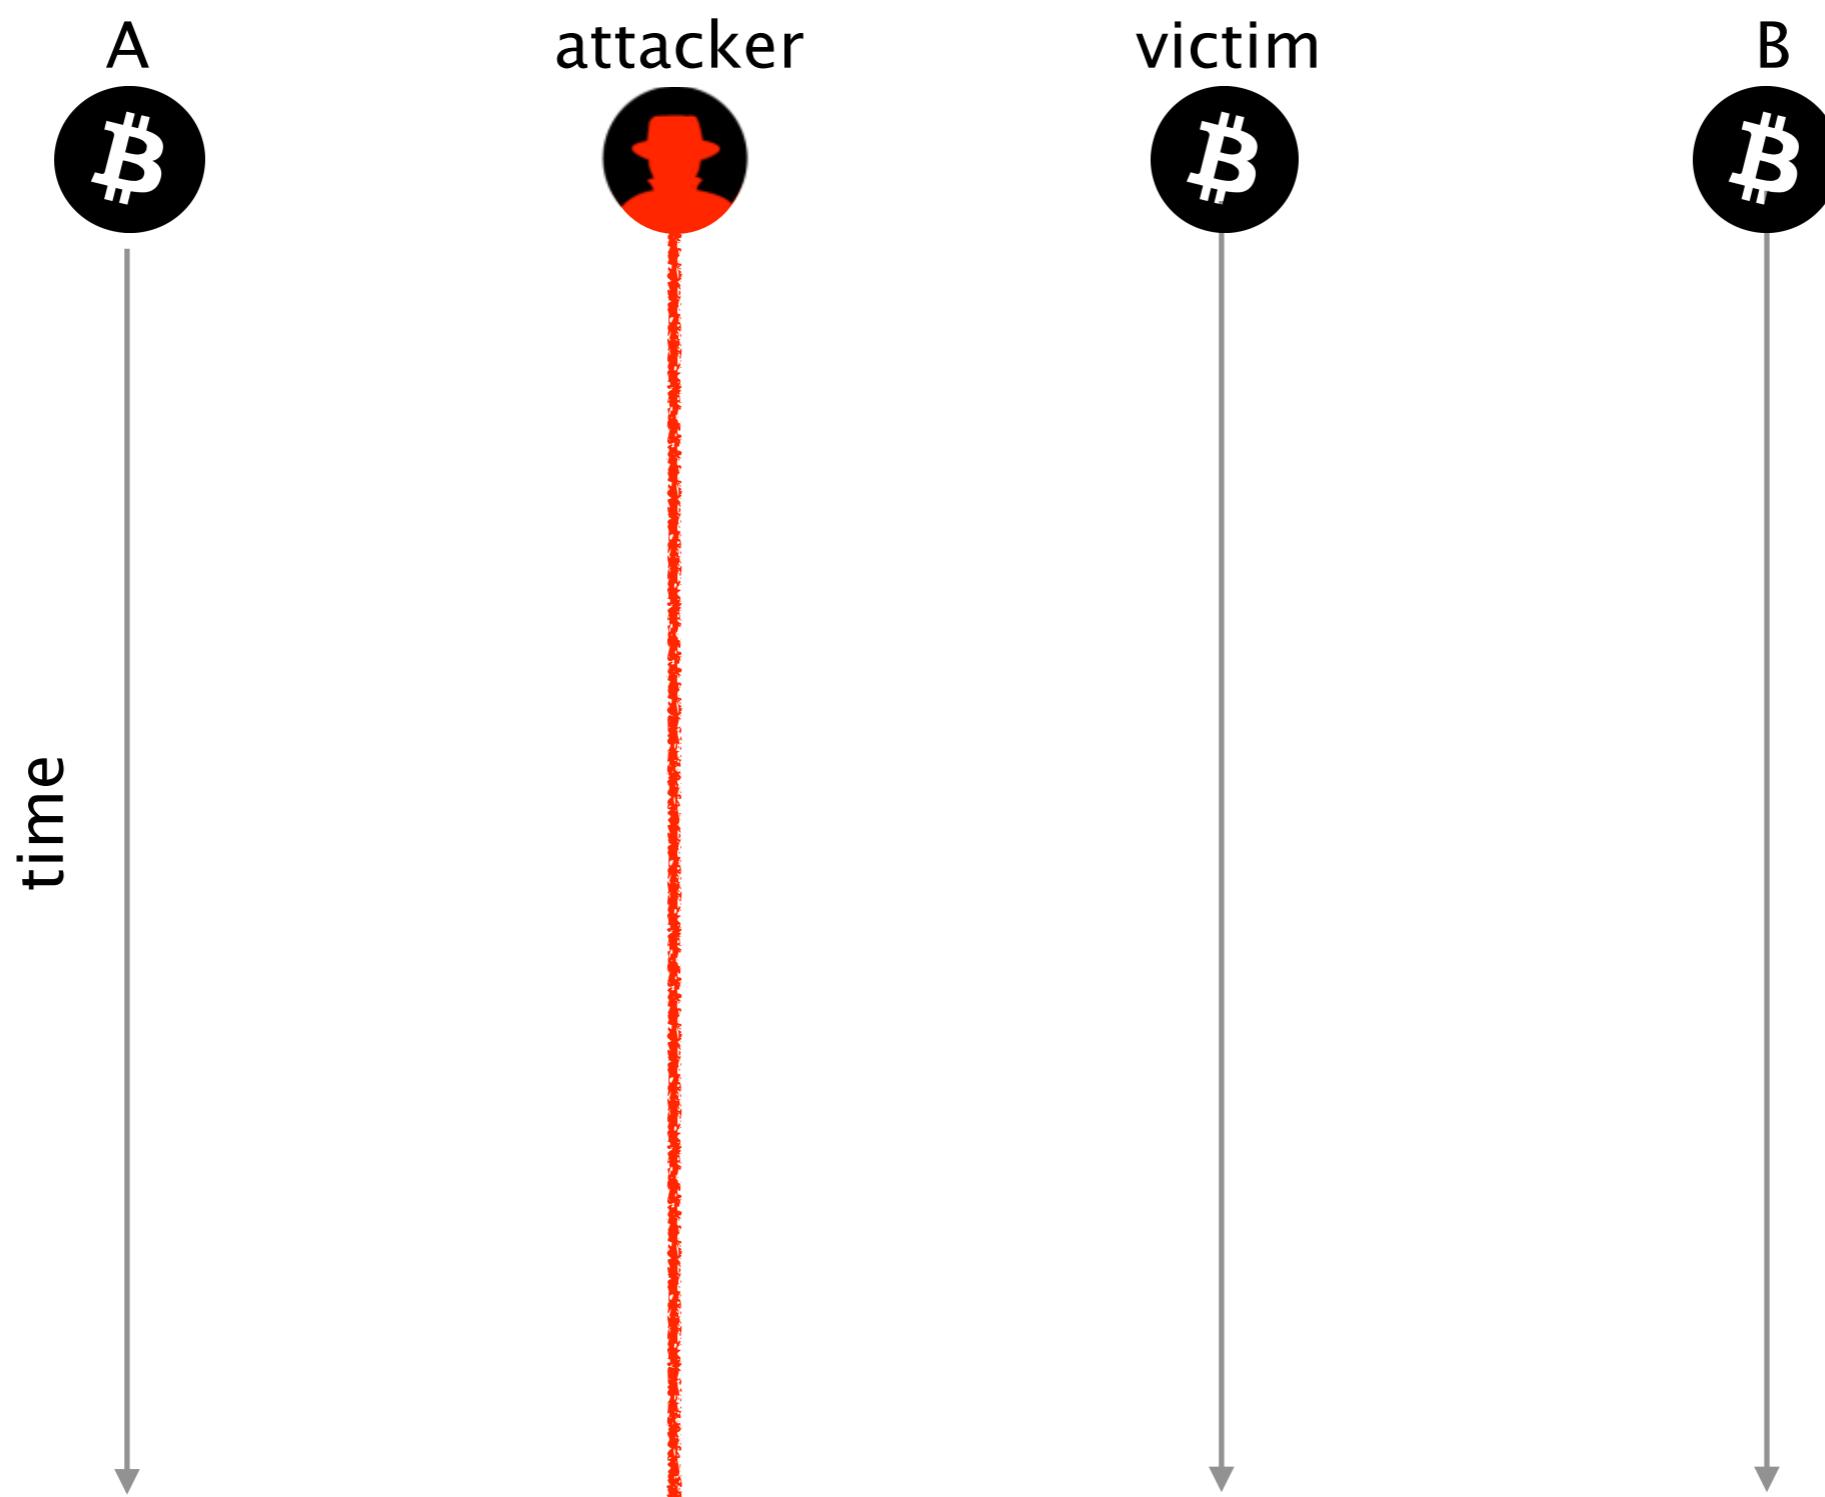

unable to collaborate to  
the peer-to-peer network

# How does a delay attack work?

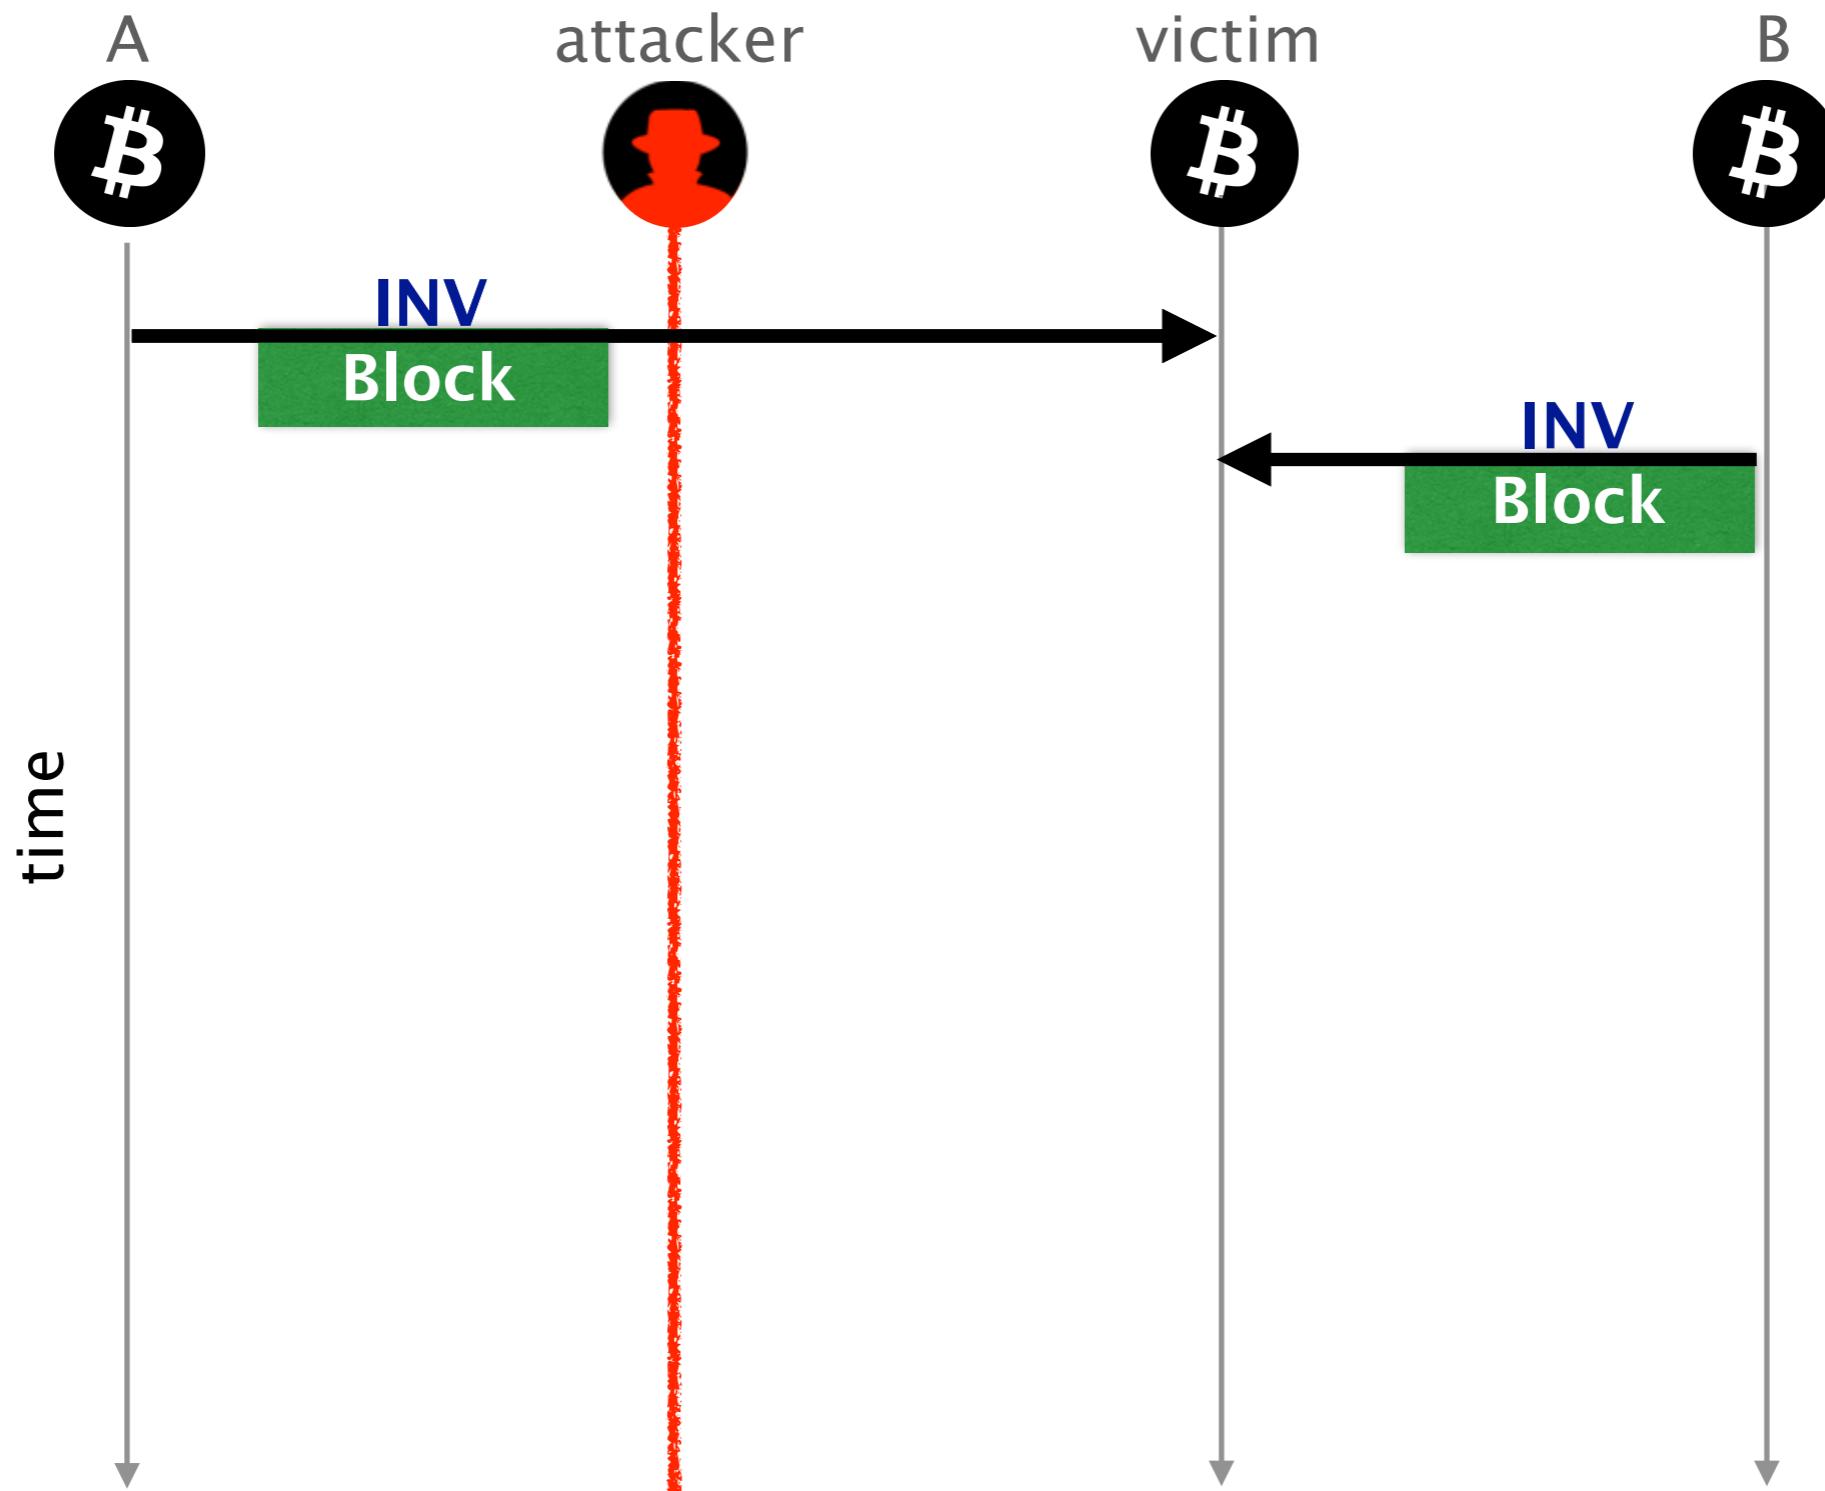

Consider these three Bitcoin nodes

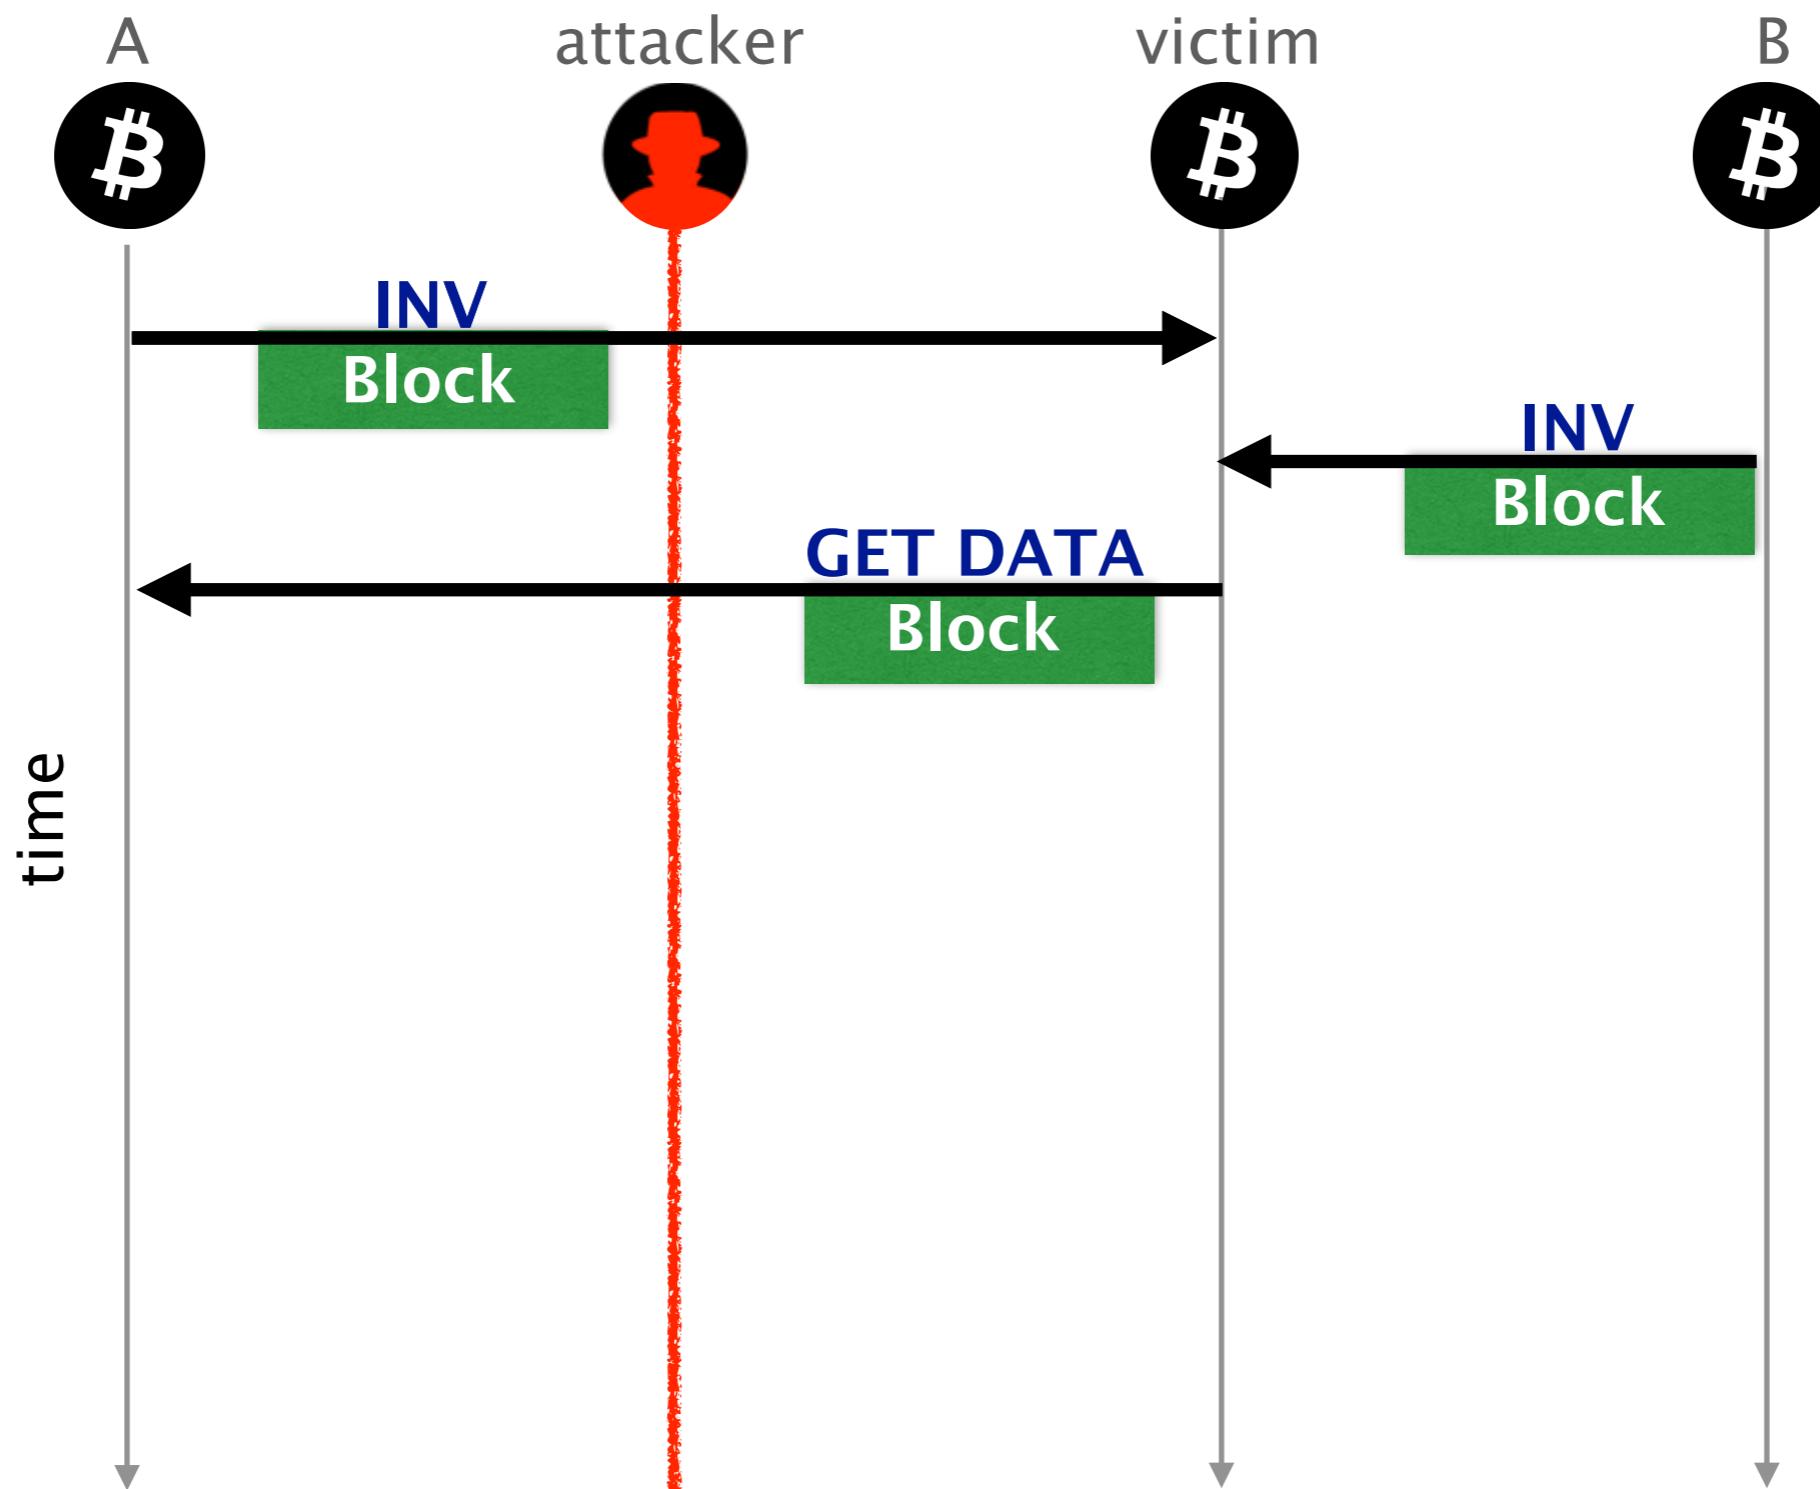

An attacker wishes to delay the block propagation towards the victim

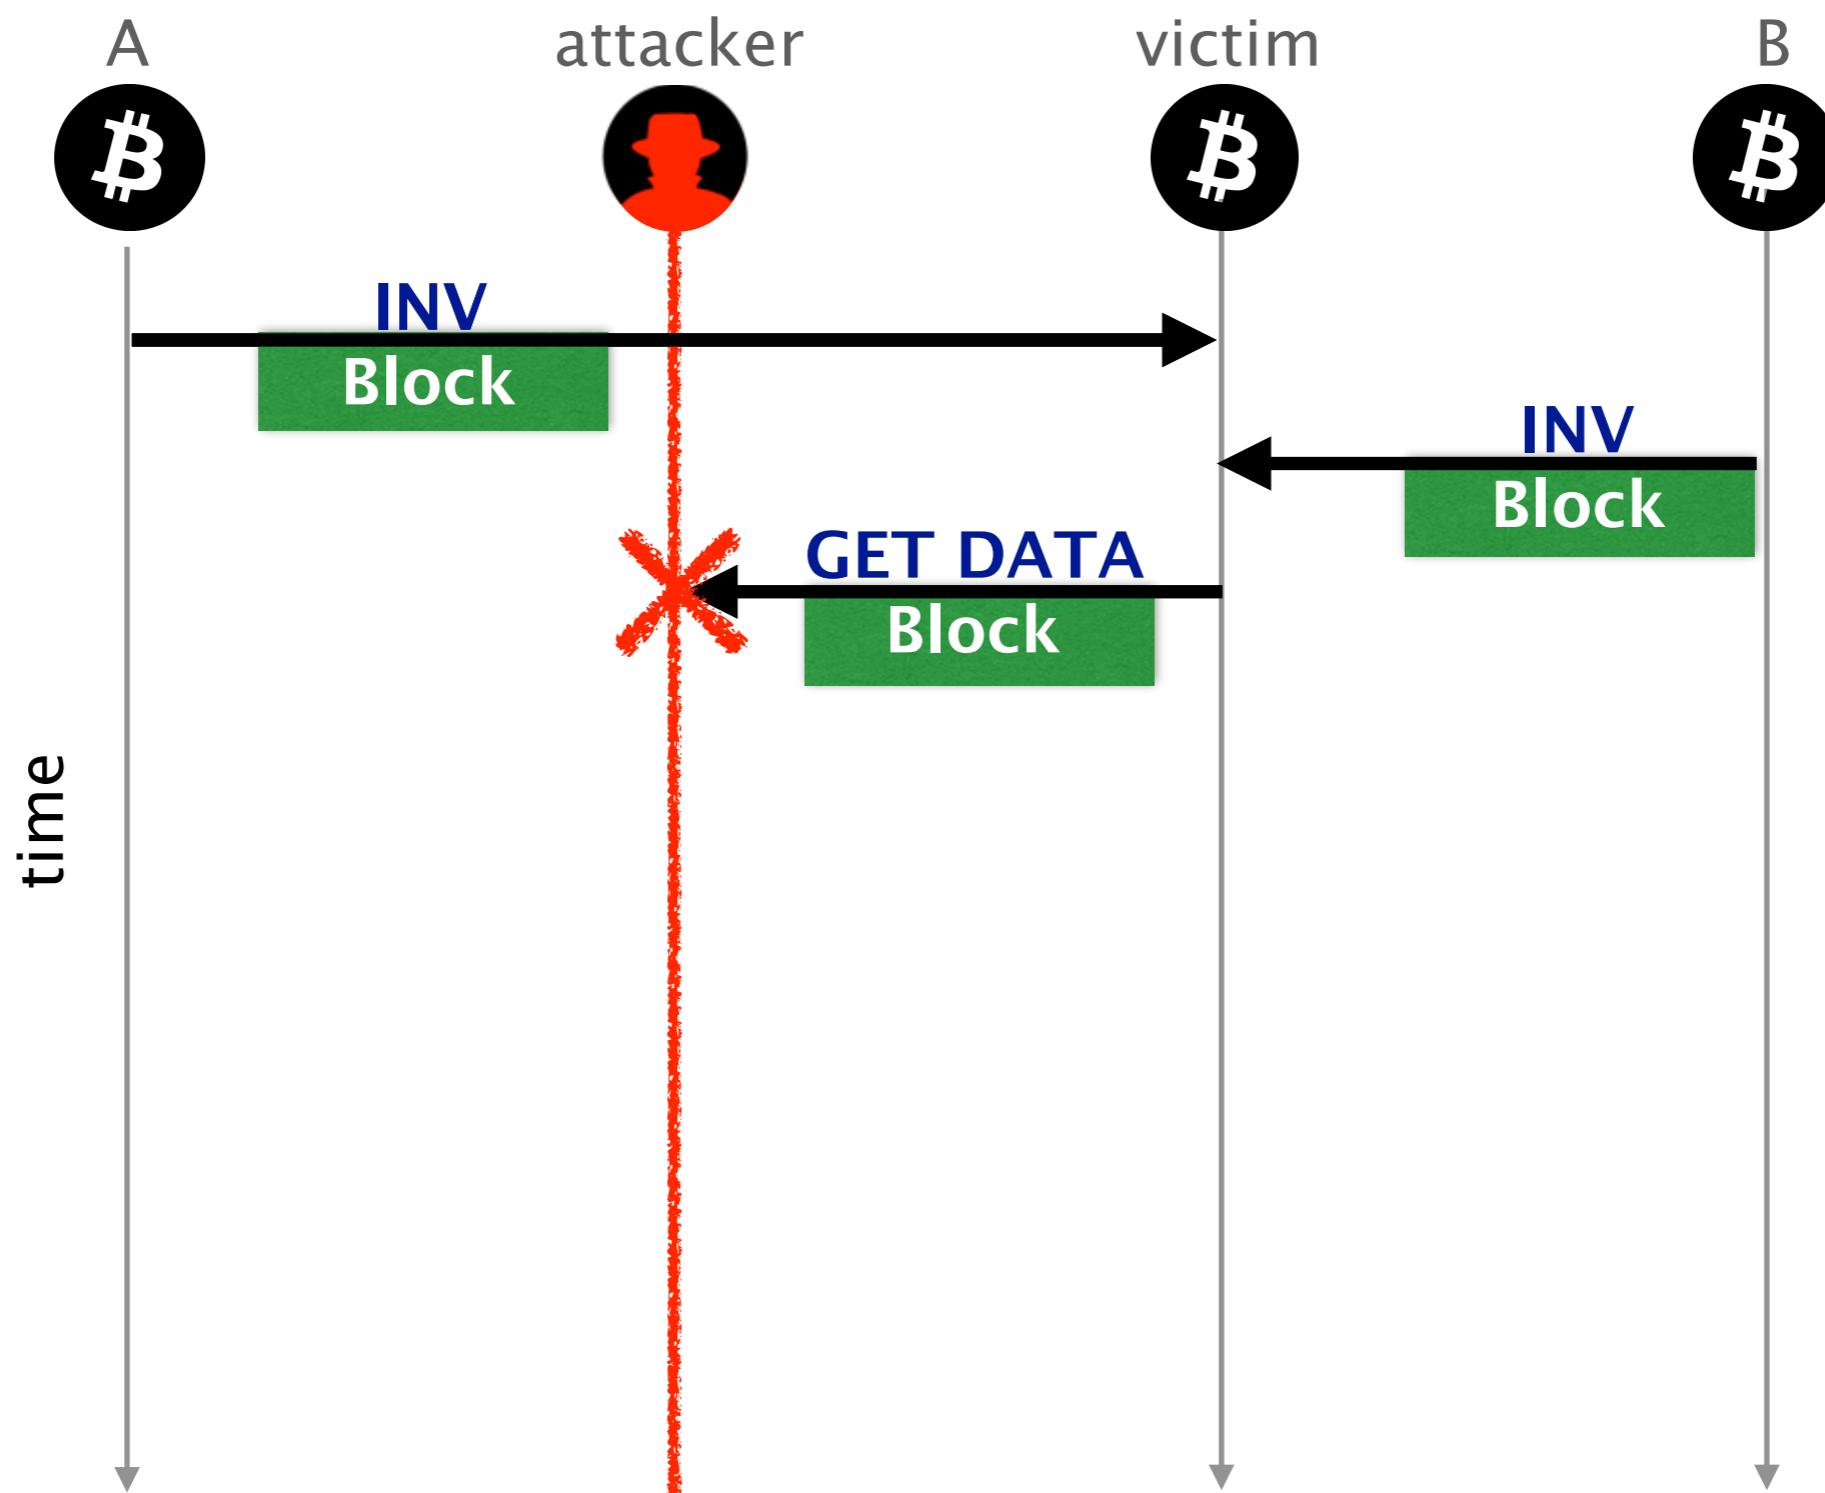

The victim receives two advertisement for the **block**

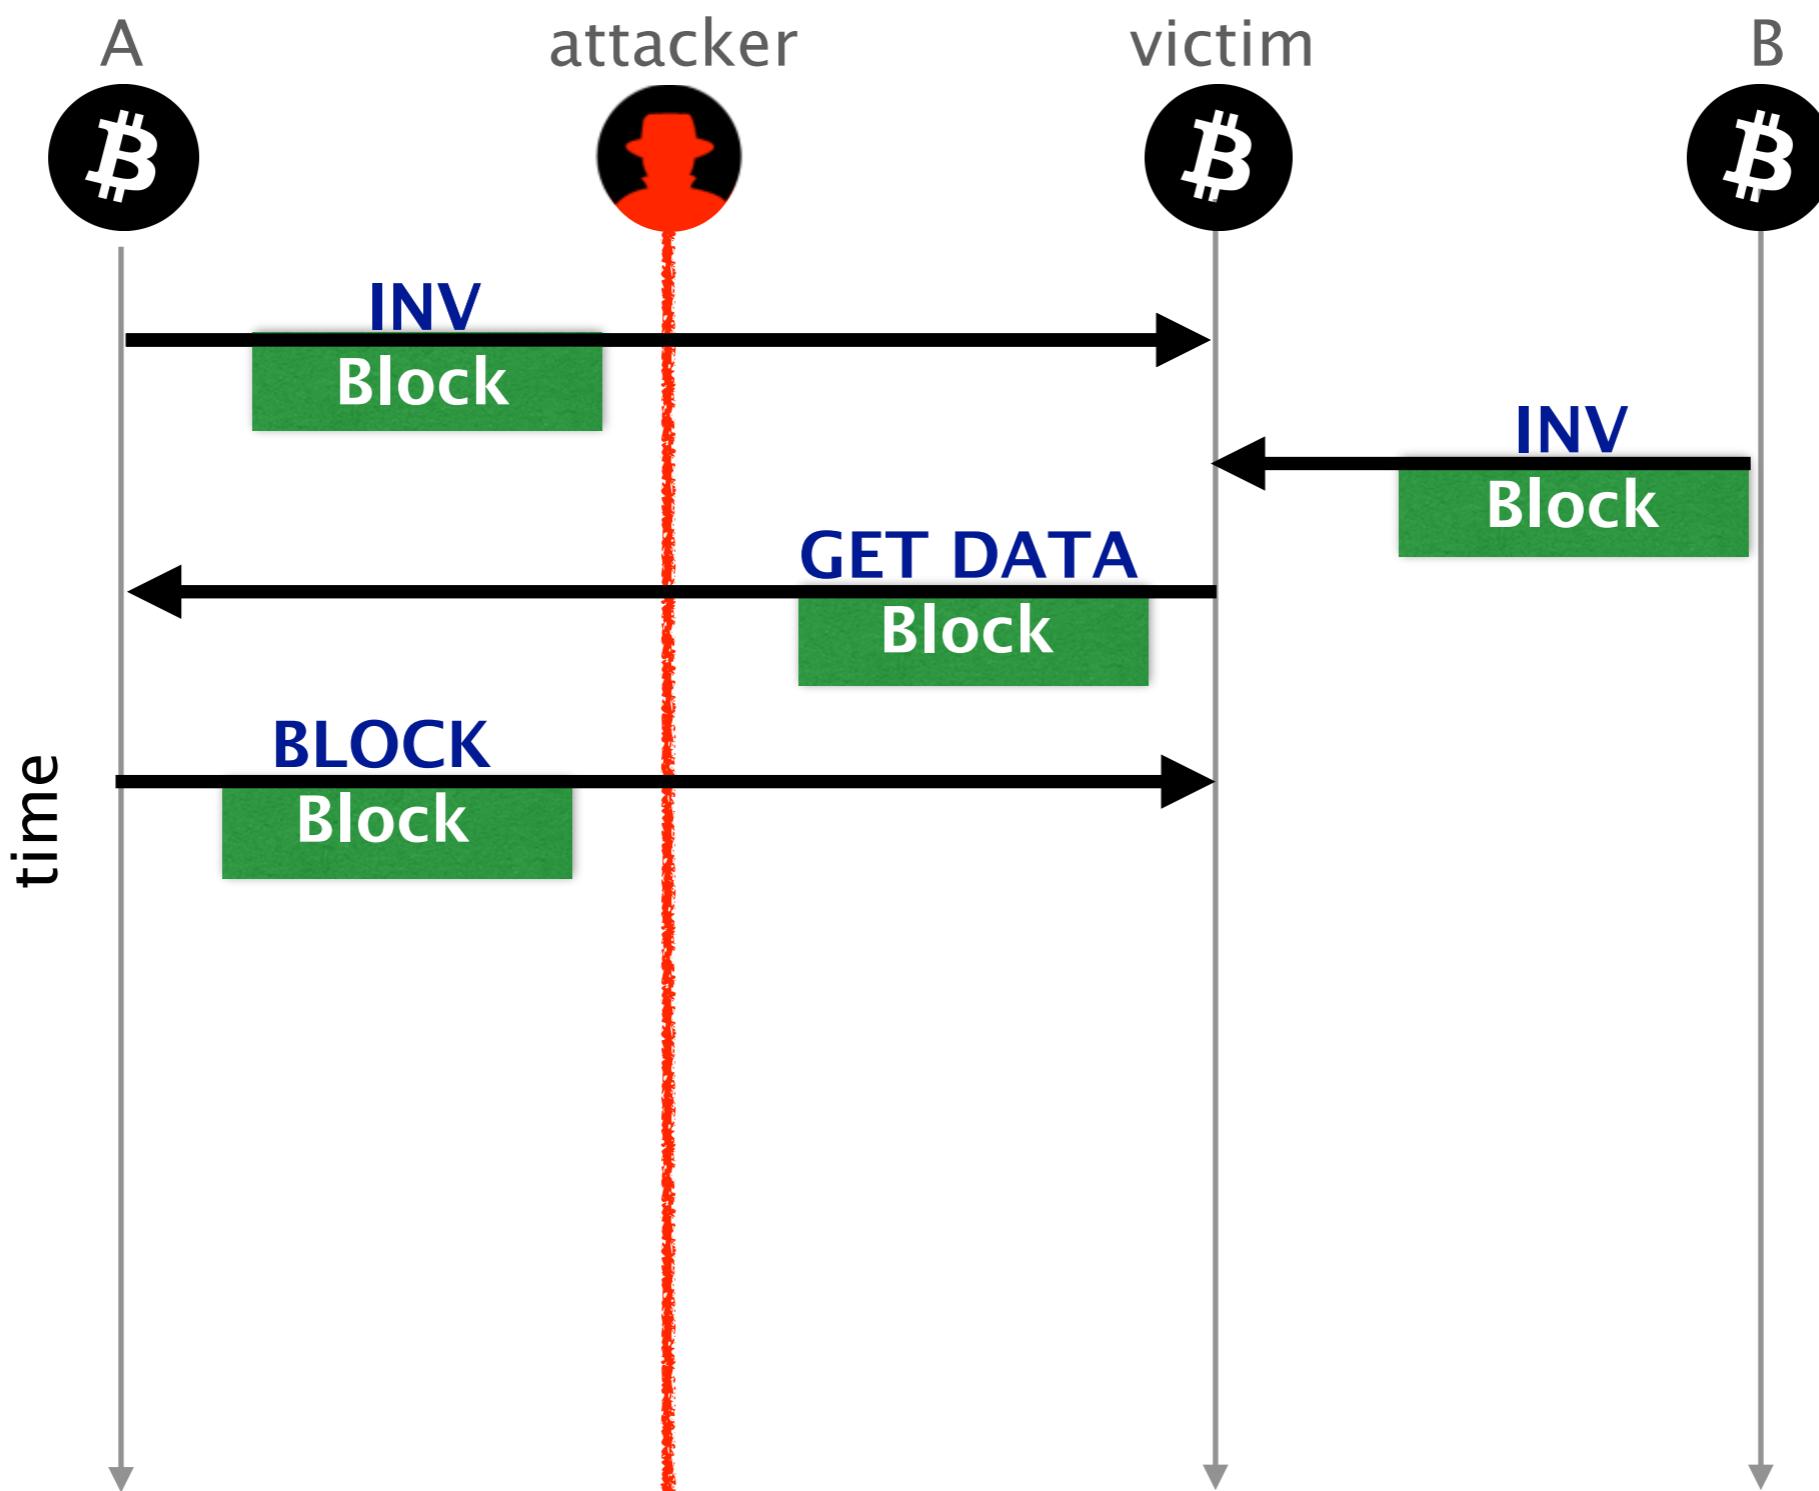

The victim requests the **block** to one of its peer, say A

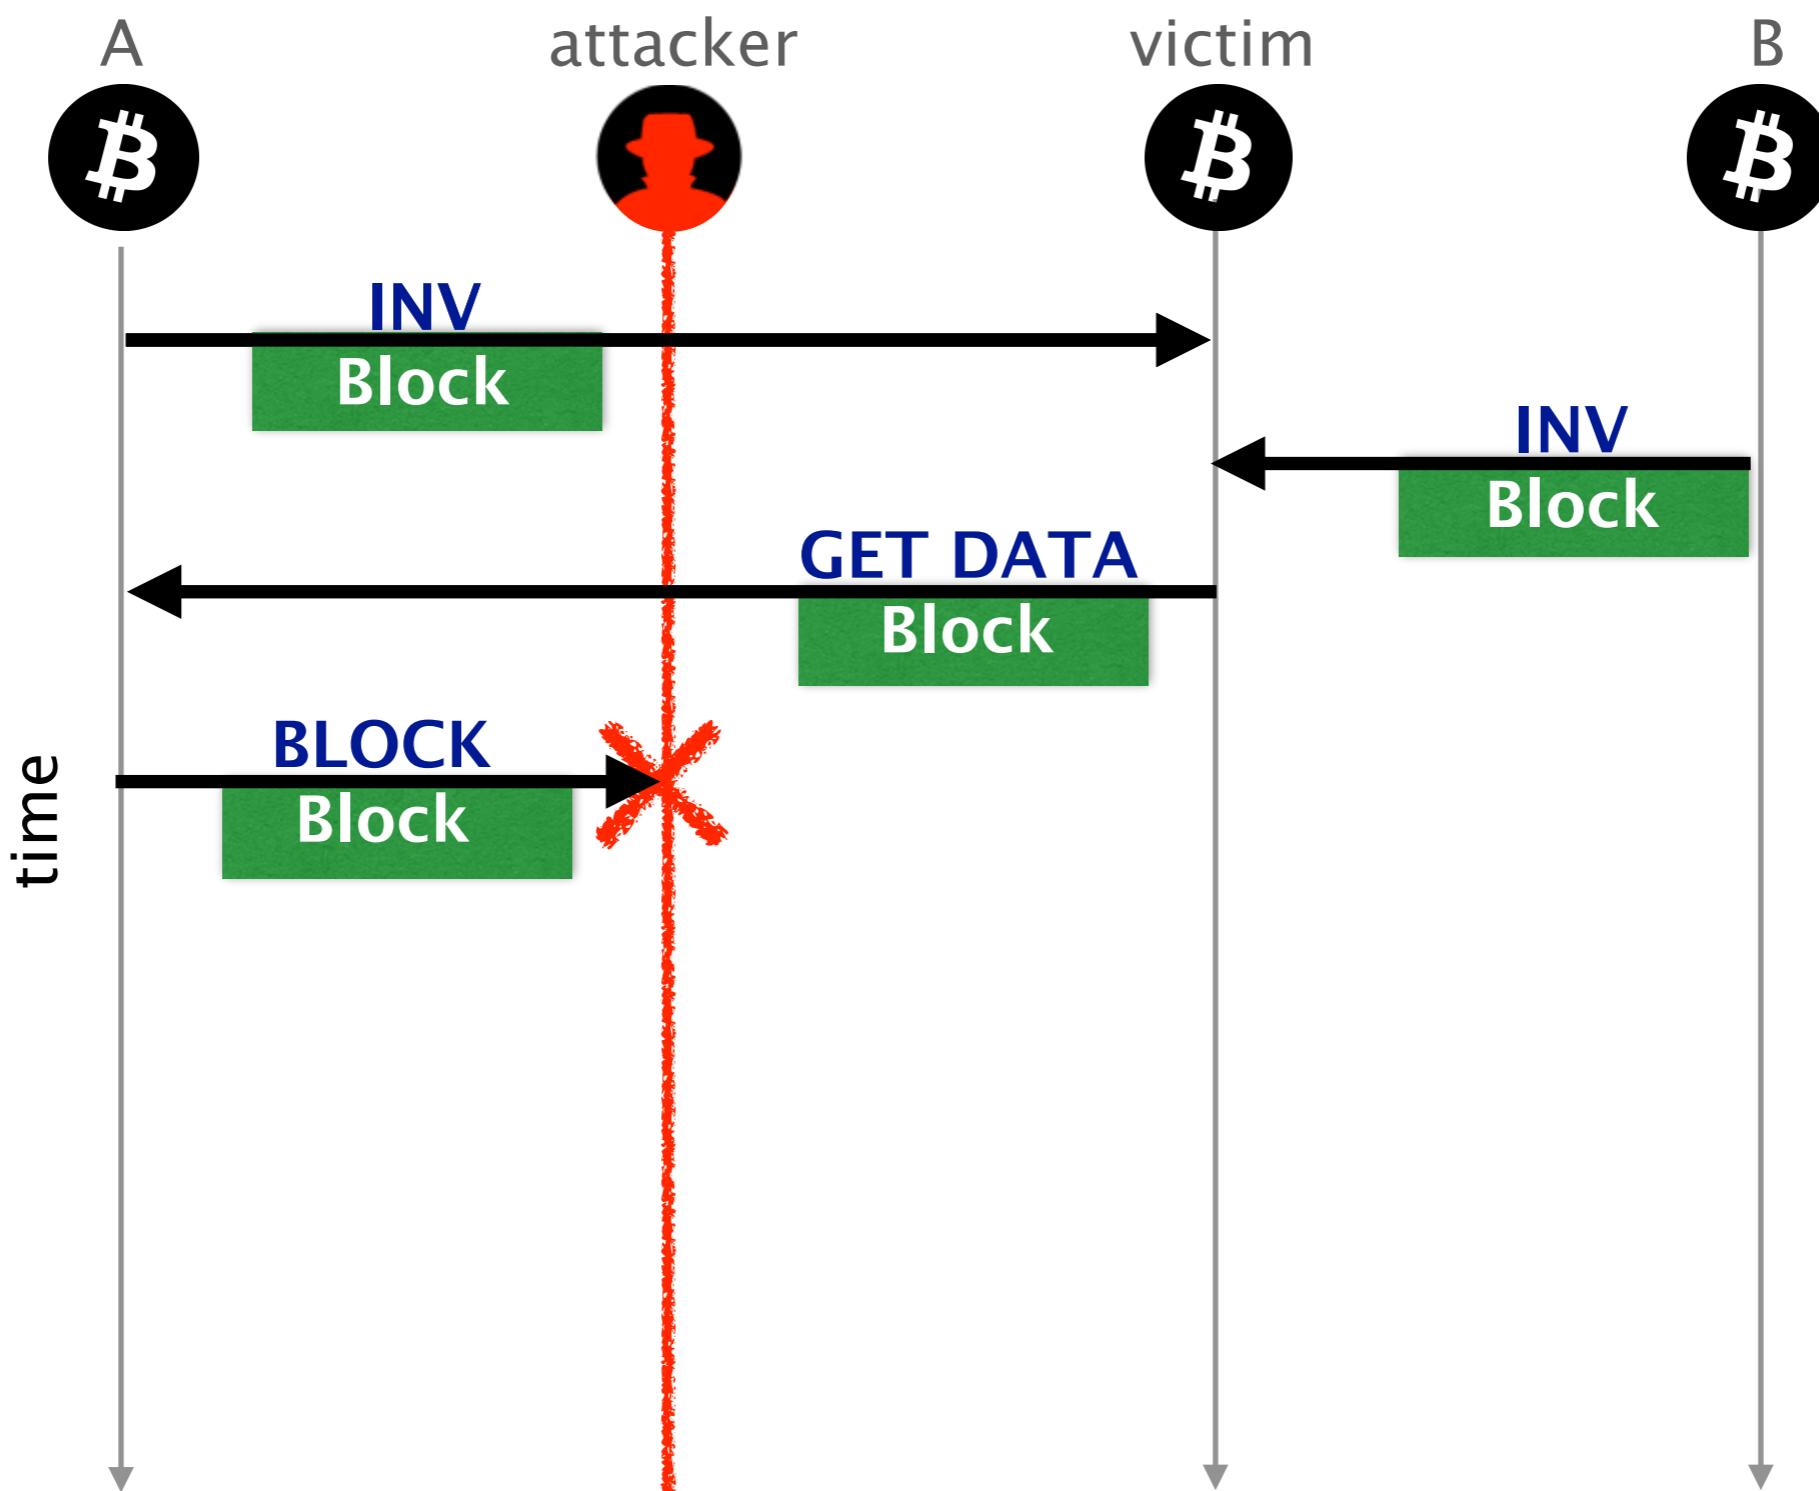

As a MITM, the attacker could drop  
the **GETDATA** message

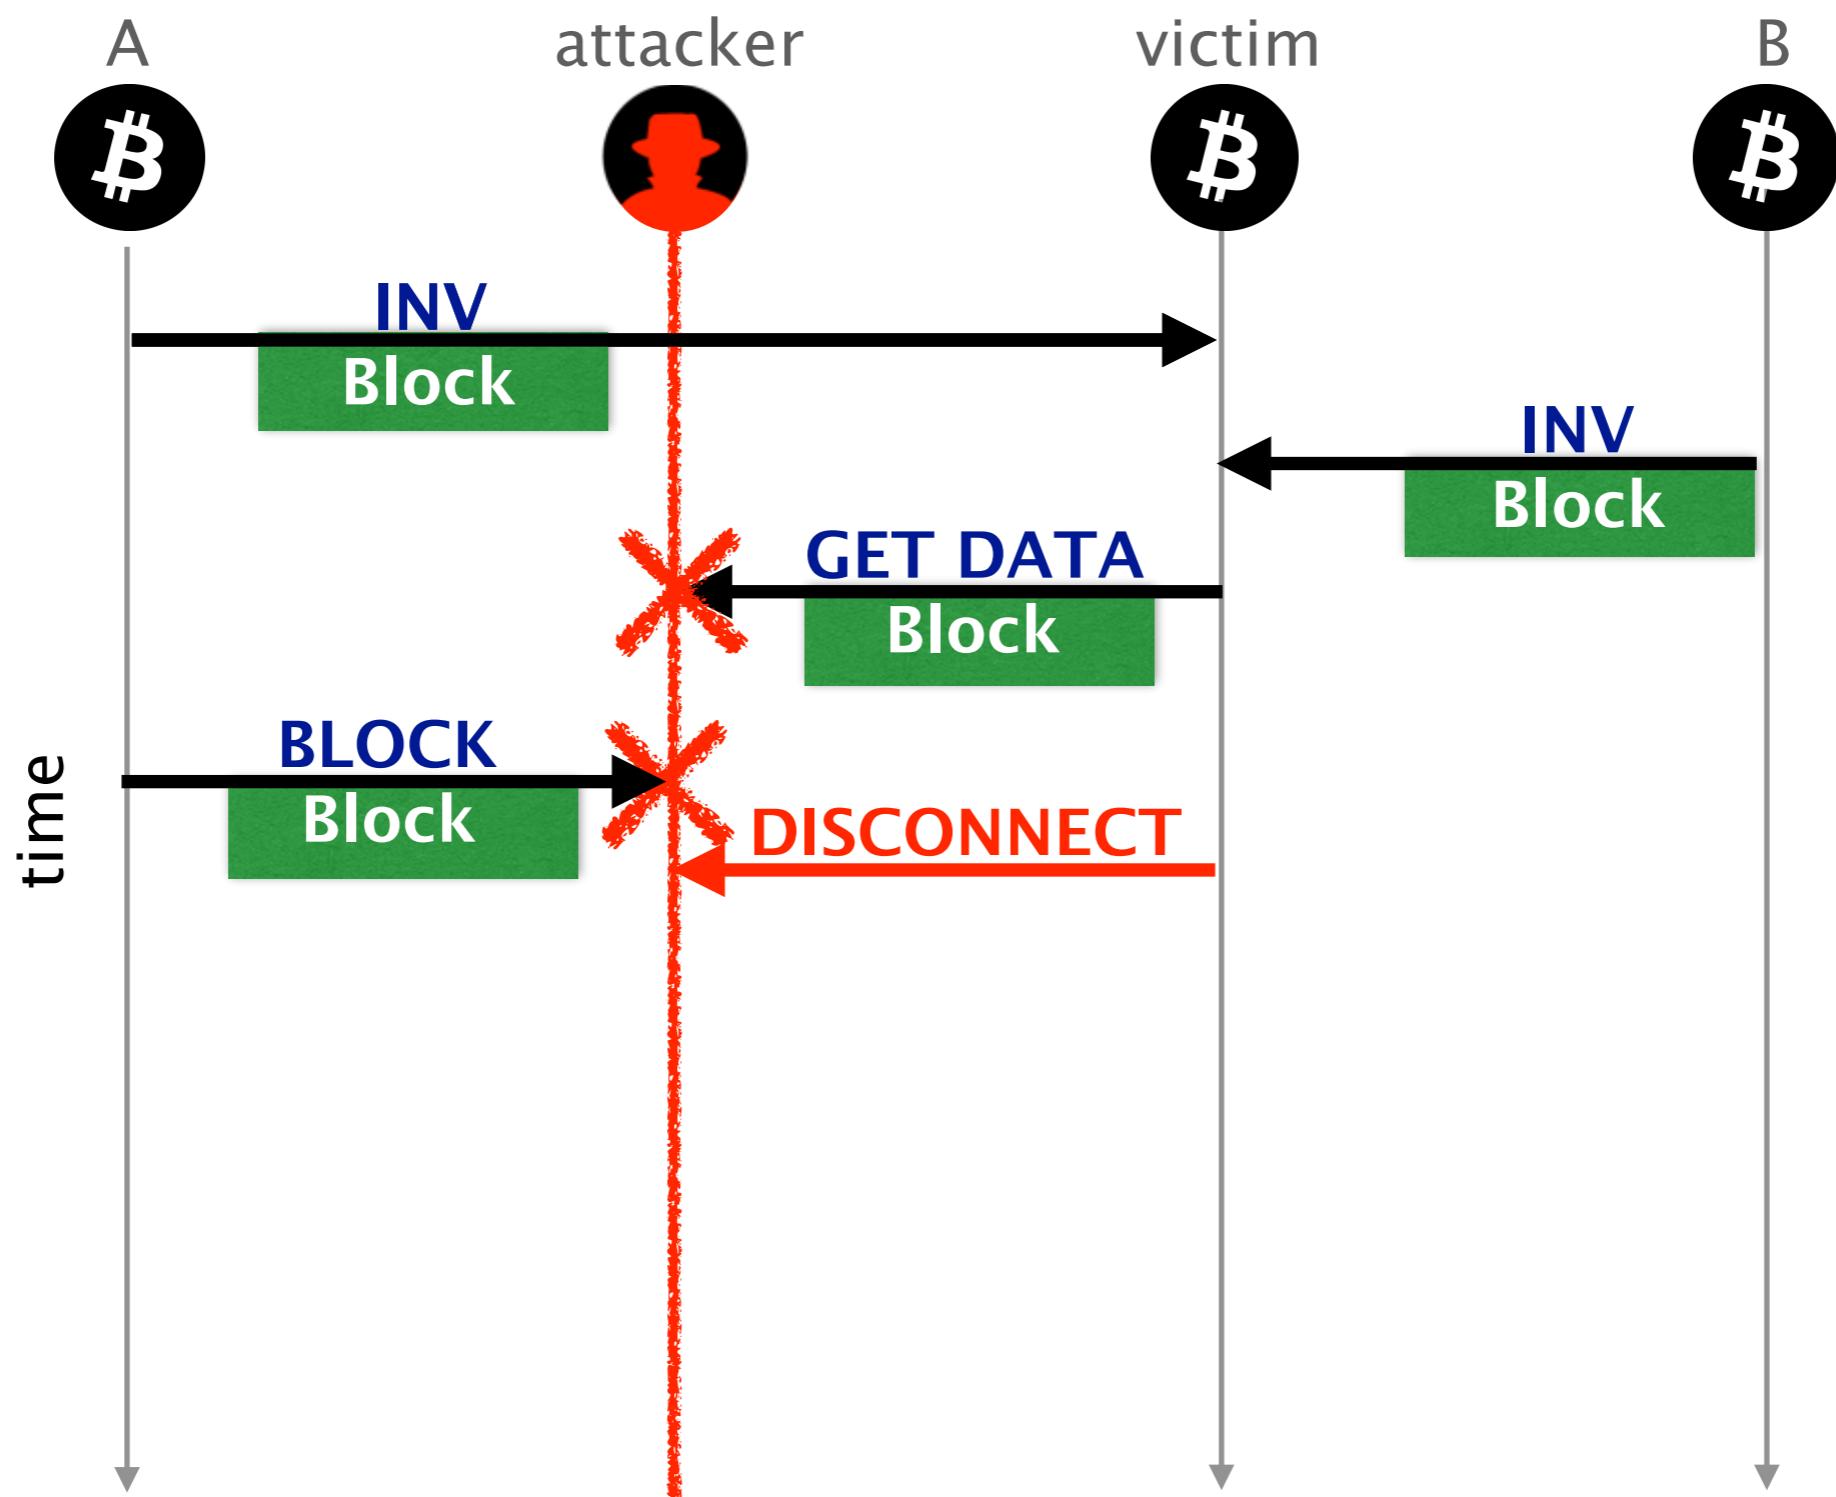

Similarly, the attacker could drop the delivery of the **block** message

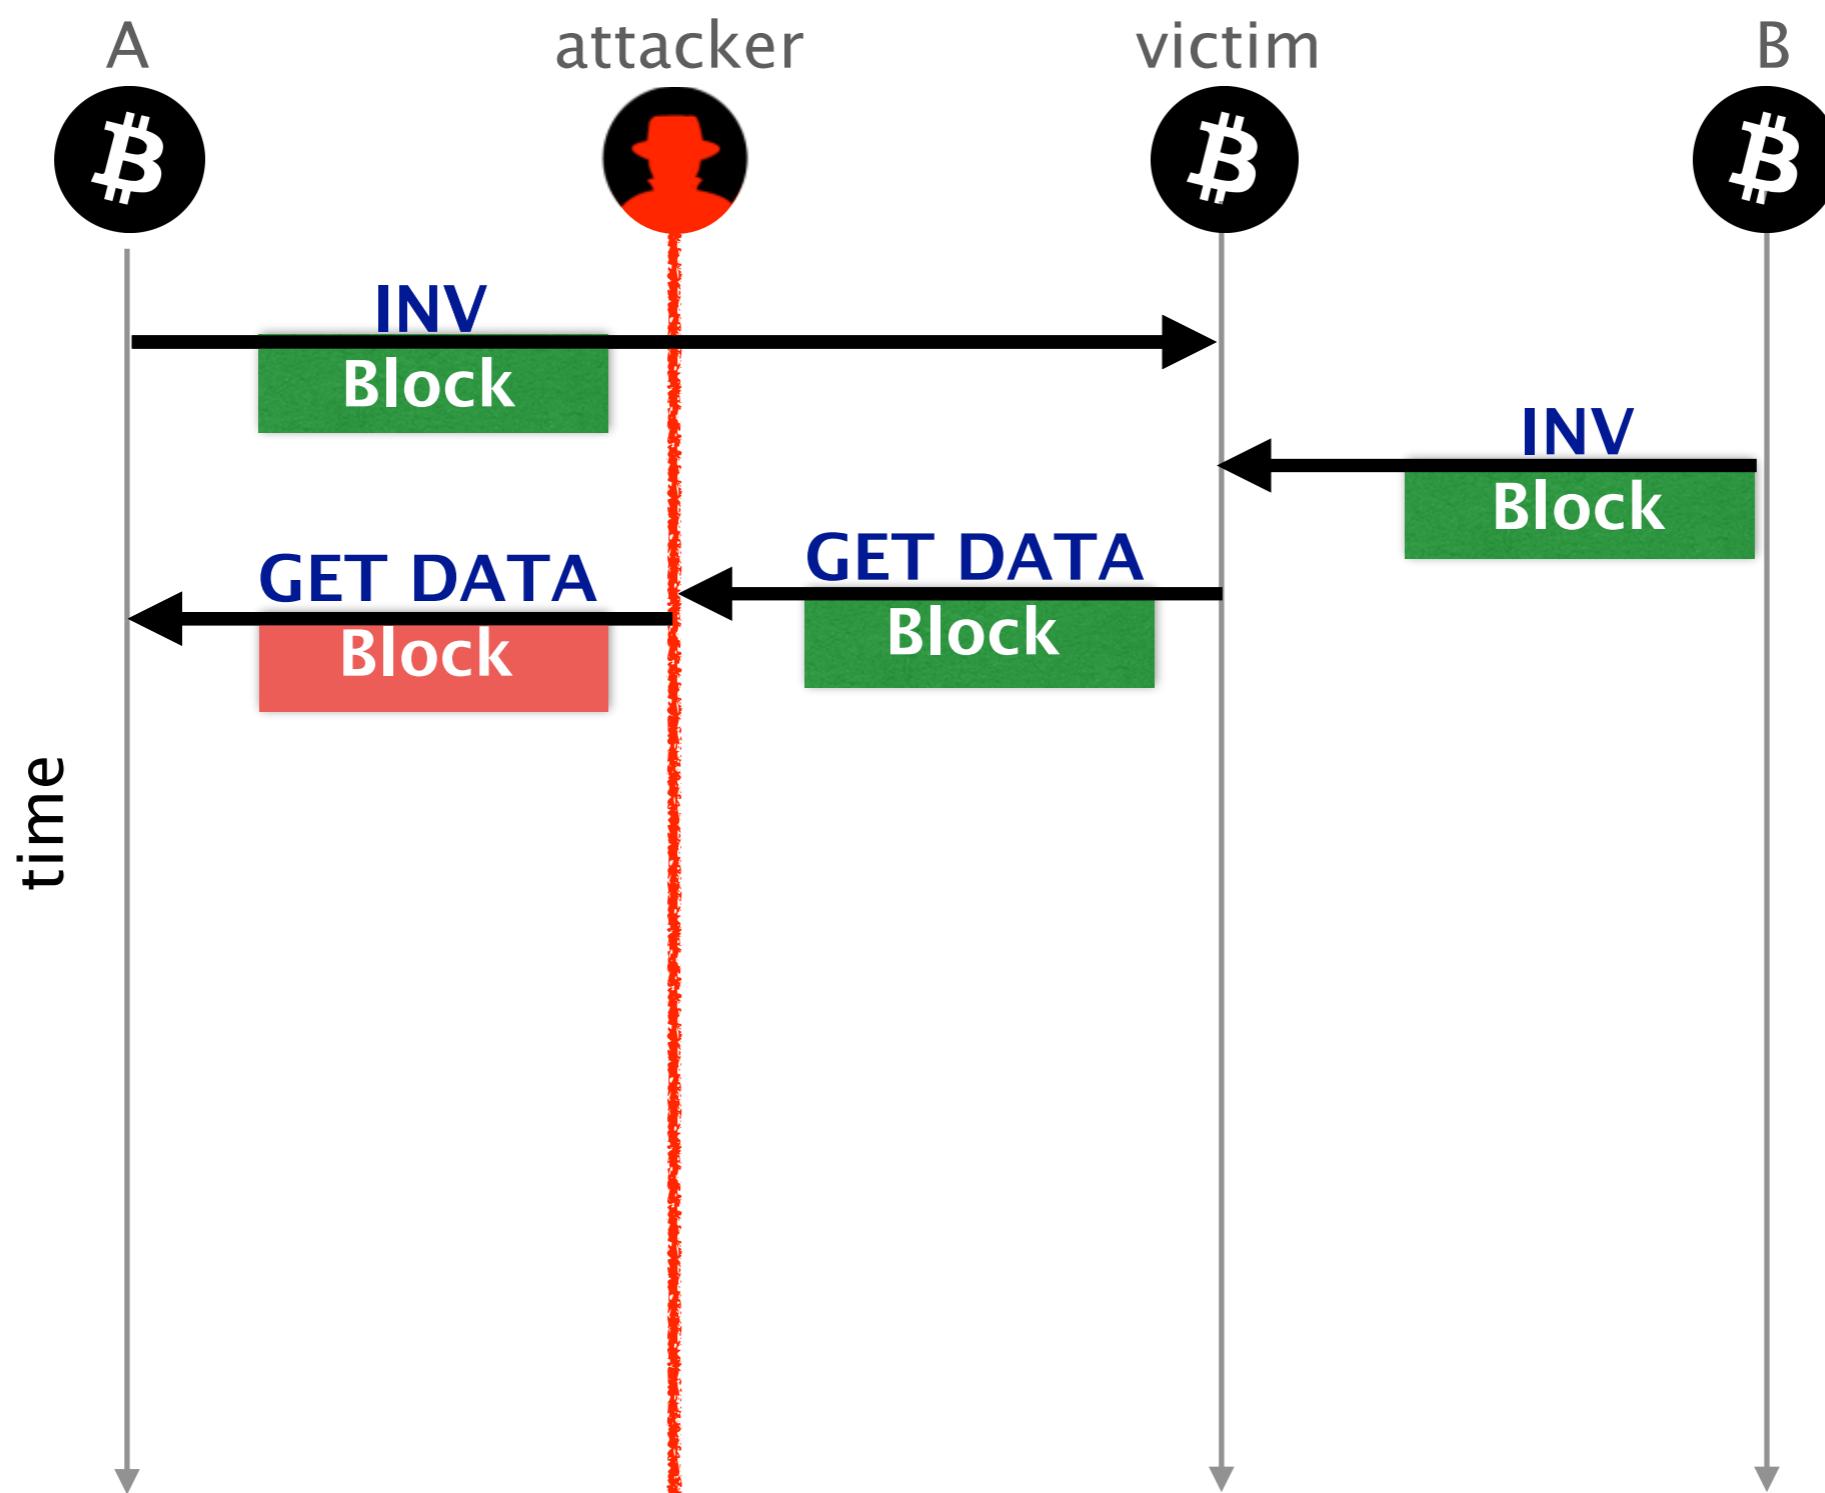

Similarly, the attacker could drop the delivery of the **block** message

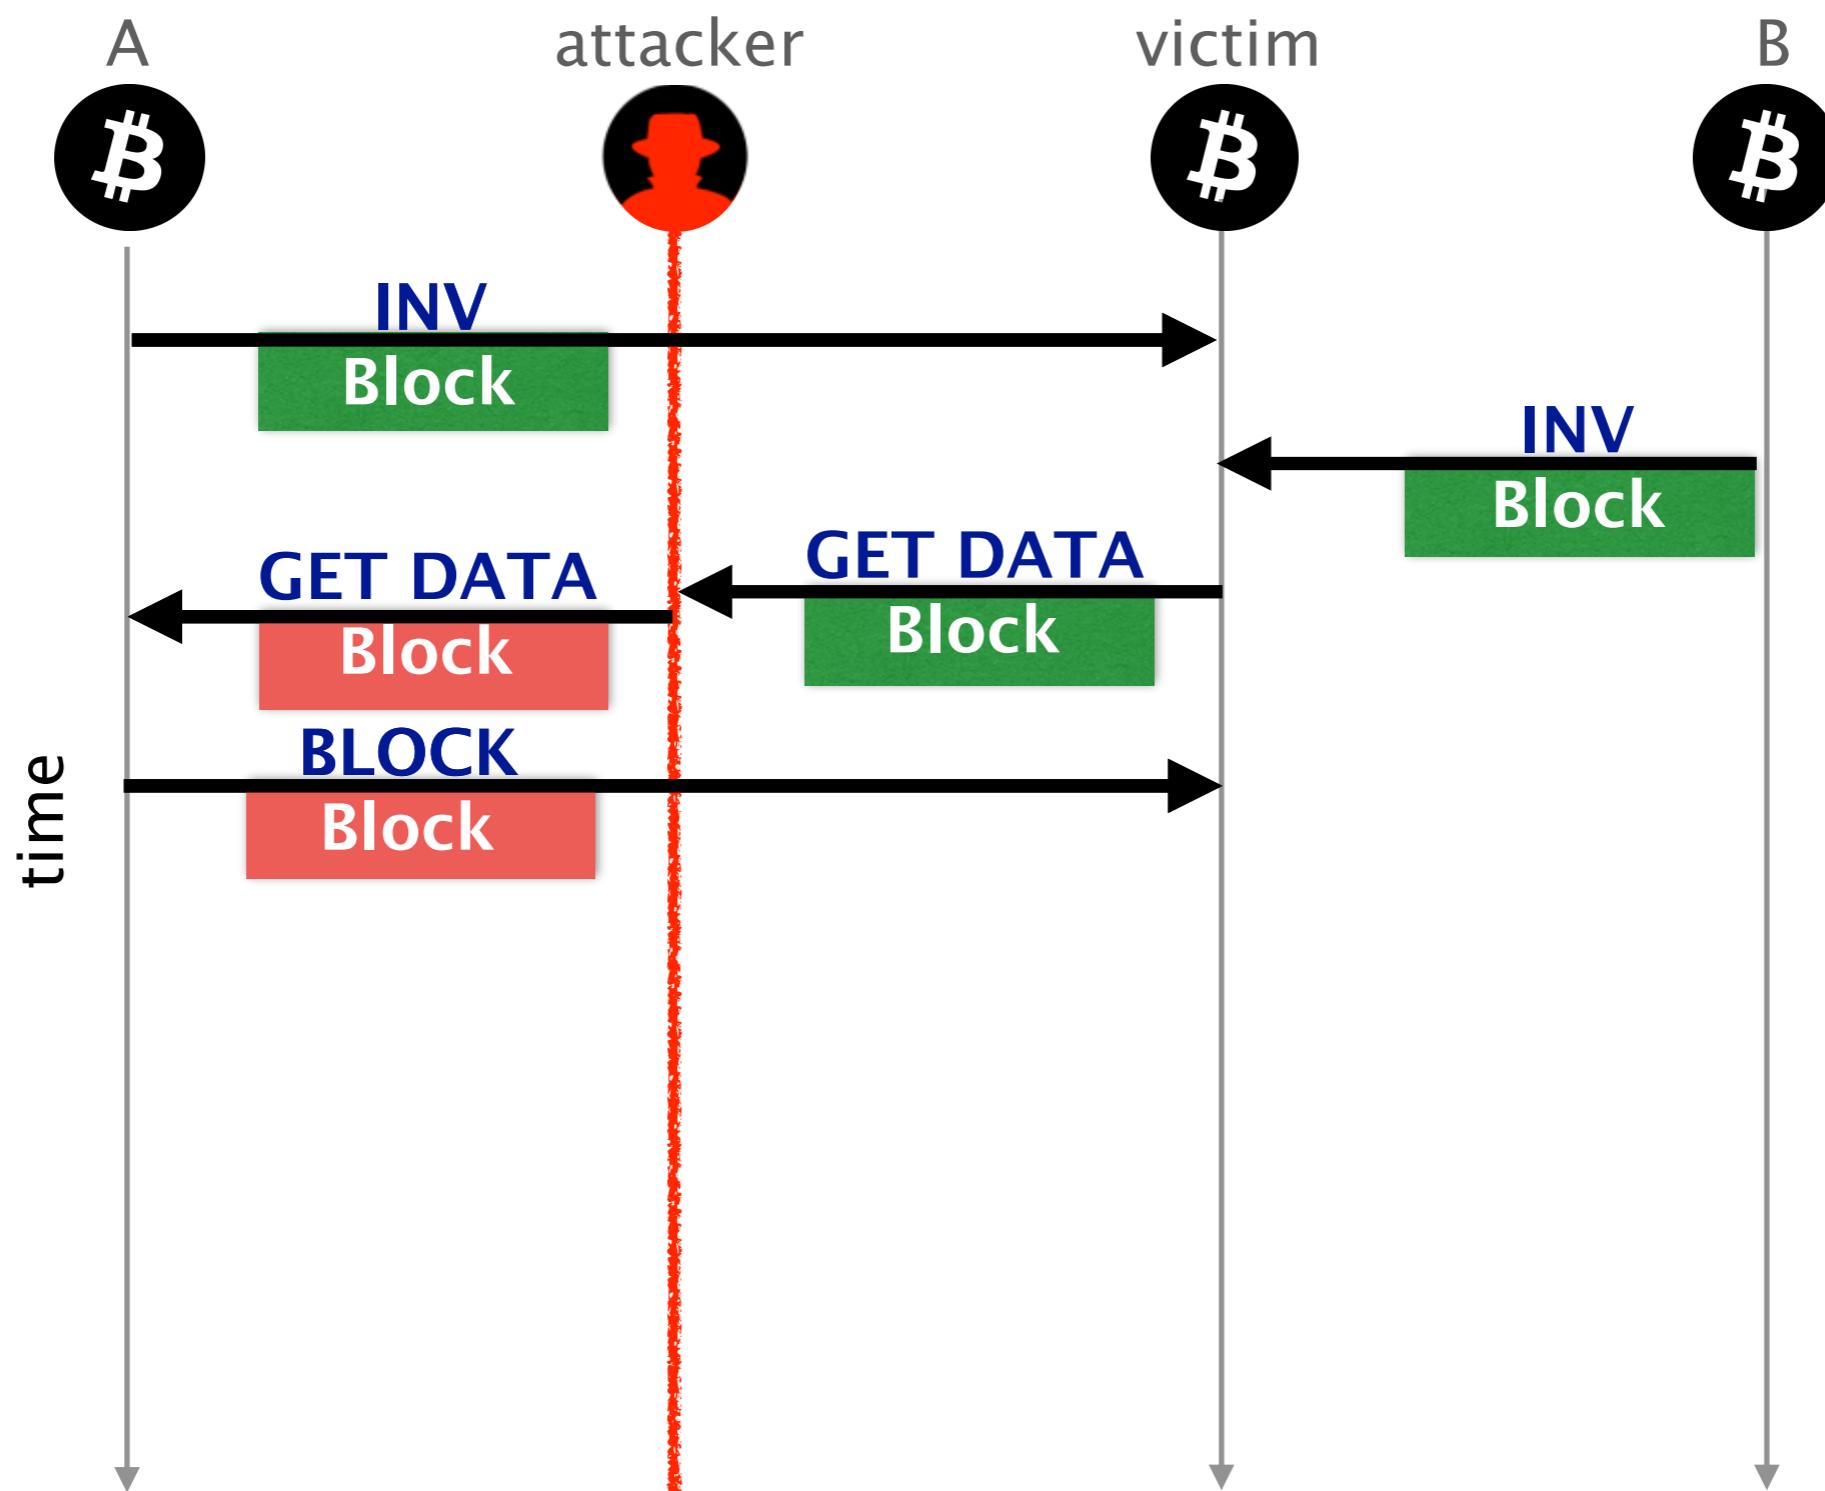

Yet, both cases will lead to the victim killing the connection (by the TCP stack on the victim)

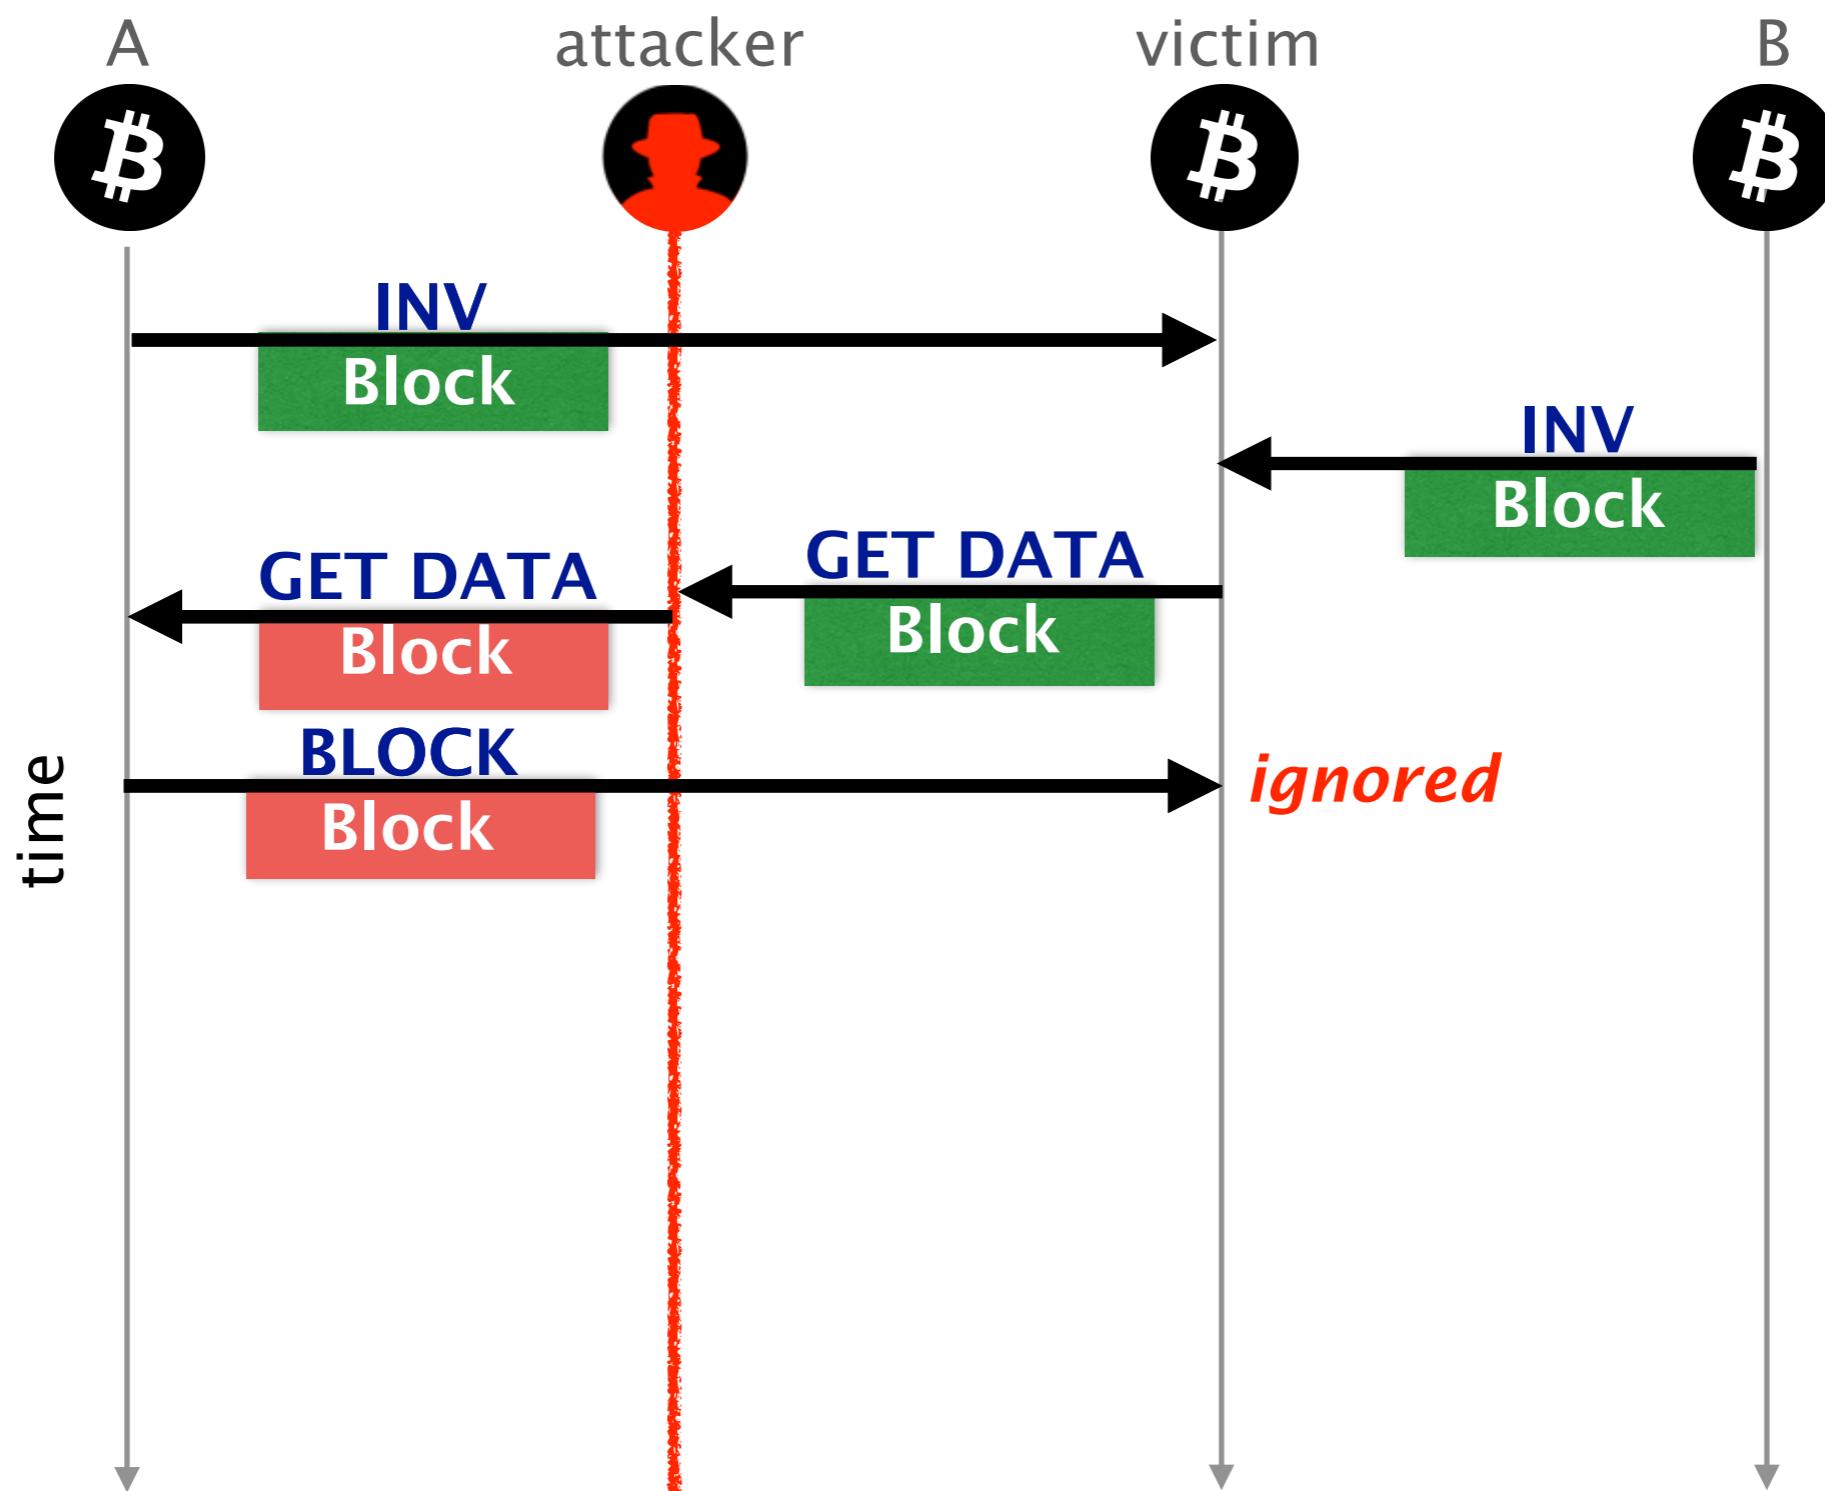

Instead, the attacker could intercept the **GETDATA** and **modifies its content**

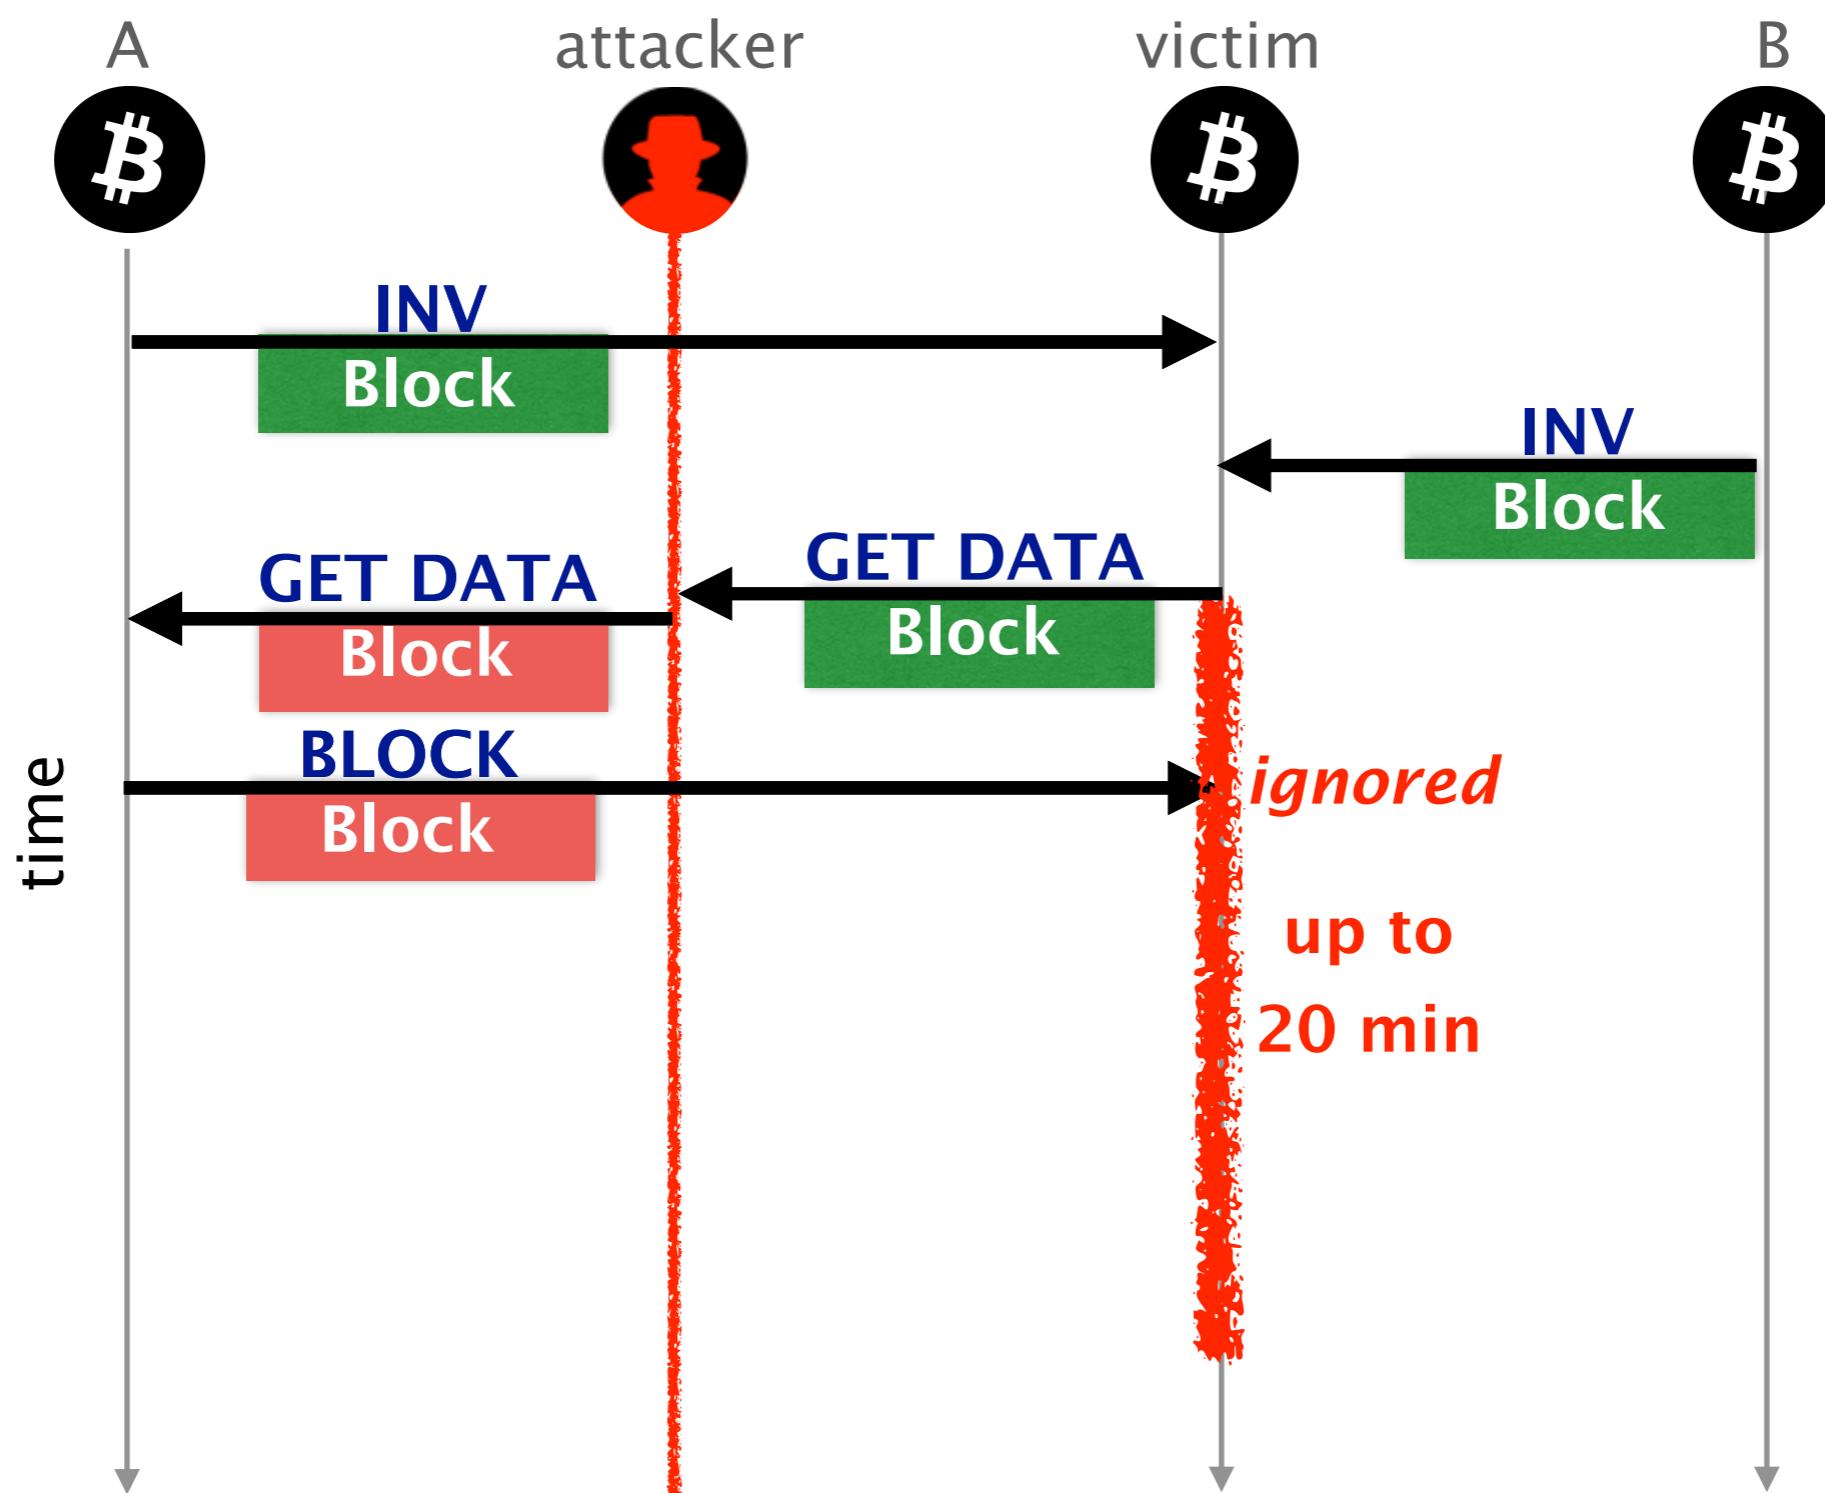

By modifying the ID of the requested block,  
the attacker triggers the delivery of an older **block**

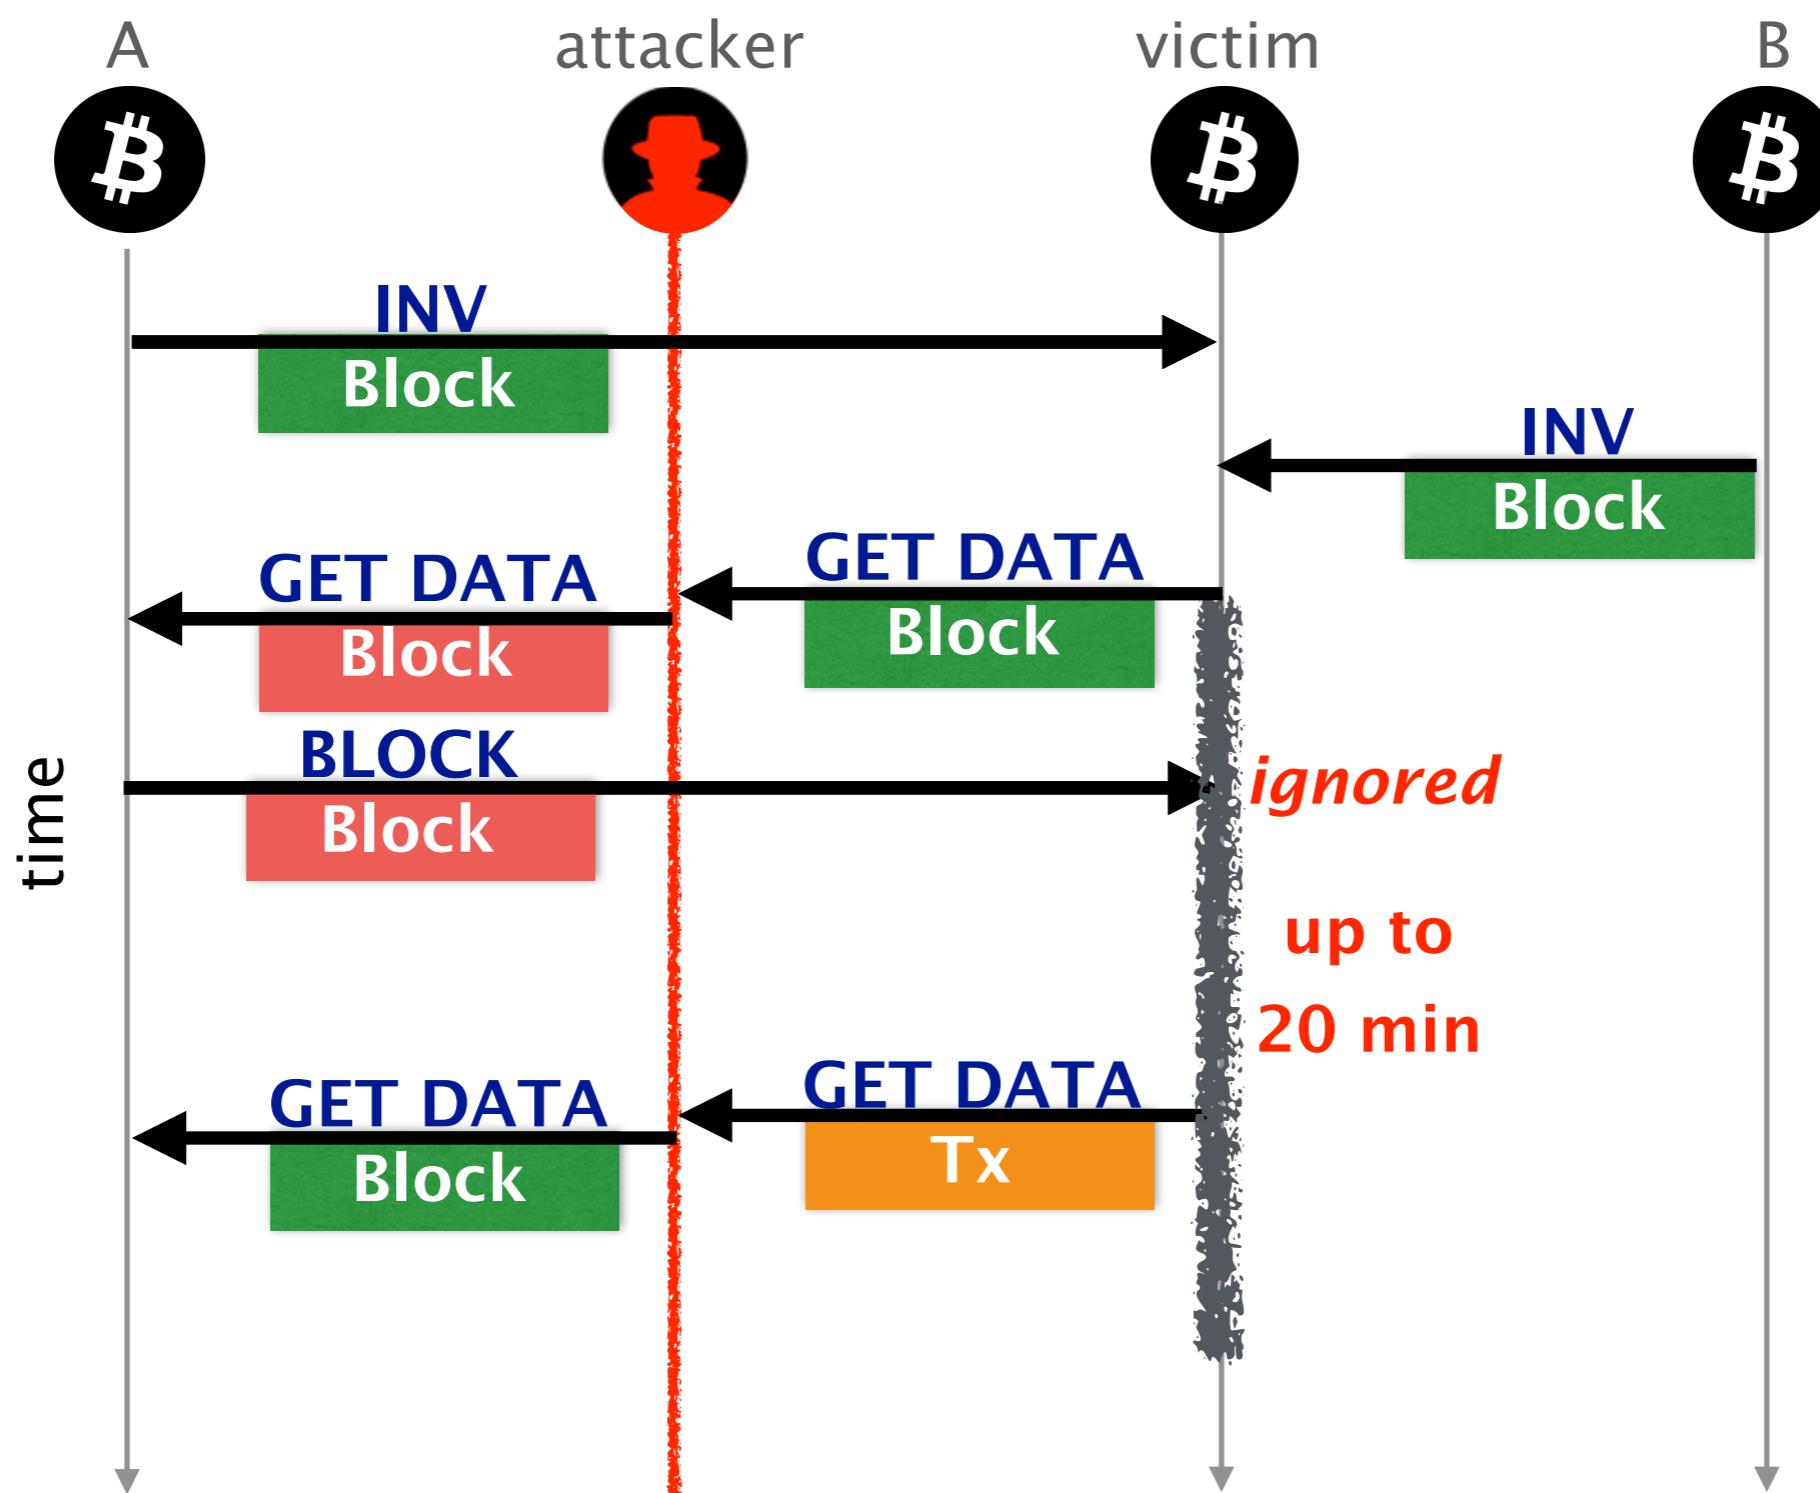

The delivery of an older block triggers  
**no error** message at the victim

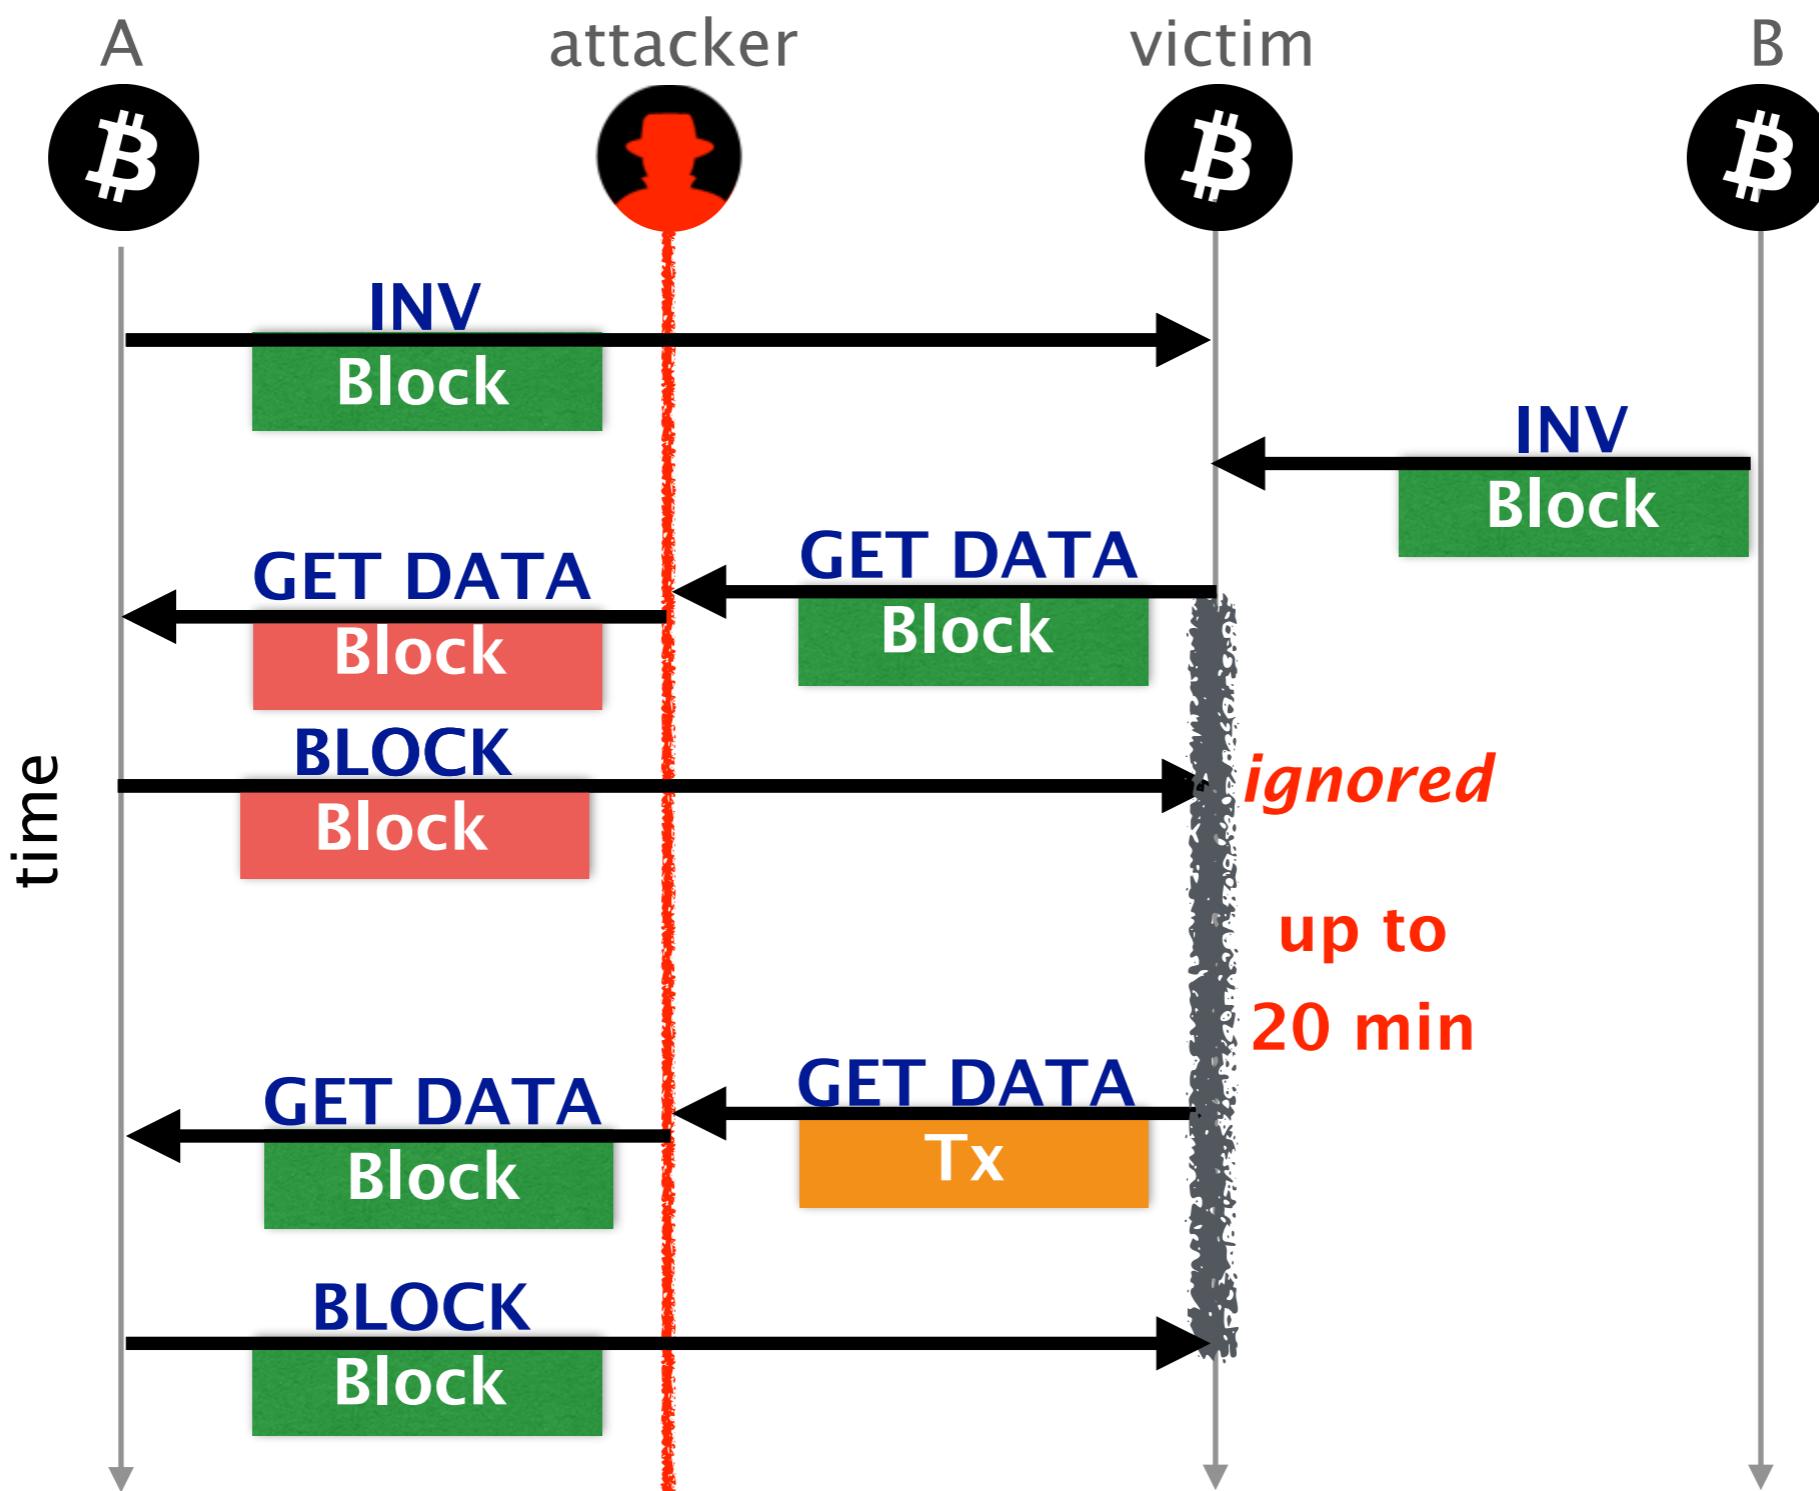

From there on, the victim will wait **for 20 minutes** for the actual block to be delivered

To keep the connection alive, the attacker can trigger the block delivery by modifying another GETDATA message

Doing so, the block is delivered before the timeout  
and the attack goes **undetected** (and could be resumed)

We evaluated the delay attack in terms of effectiveness and practicality

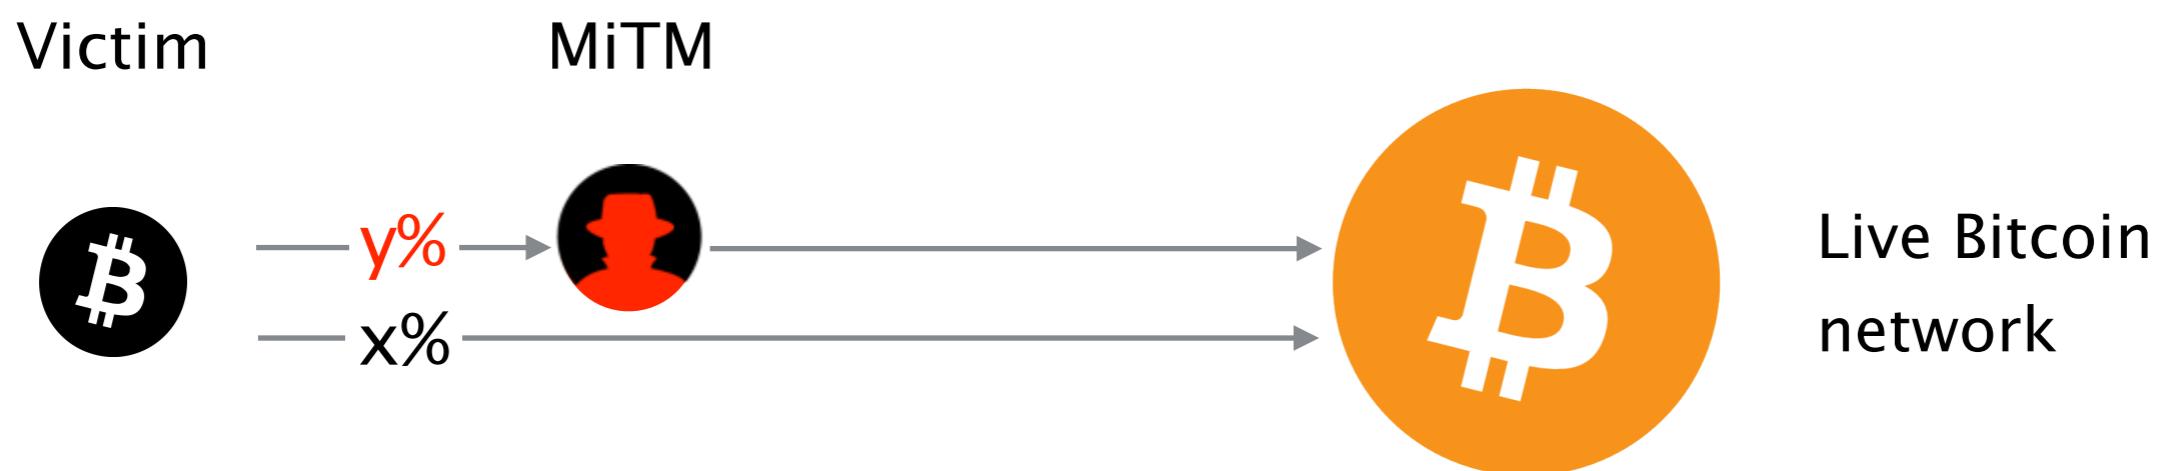

### Effectiveness

How much time does  
the victim stay uninformed?

### Practicality

Is it likely to happen?

We performed the attack  
on a percentage of a node's connections (\*)

(\*) software available online: <https://btc-hijack.ethz.ch/>

The attacker can keep the victim uninformed  
for most of its uptime while staying under the radar

The attacker can keep the victim uninformed  
for most of its uptime while staying under the radar

even if the attacker intercepts  
a fraction of the node connection

% intercepted connections 50%

% intercepted connections	50%
% time victim does not have the most recent block	63.2%

# The vast majority of the Bitcoin network is at risk

% intercepted connections	50%
% time victim does not have the most recent block	63.2%
% nodes vulnerable to attack	67.9%

# Hijacking Bitcoin

## Routing Attacks on Cryptocurrencies

- 1 **Background**  
BGP & Bitcoin
- 2 **Partitioning attack**  
splitting the network
- 3 **Delay attack**  
slowing the network down
- 4 **Countermeasures**  
short-term & long-term

Both sort-term and long-term countermeasures exist

# Short-term countermeasures are simple shifts in the Bitcoin clients

Short-term

Routing-aware peer selection  
reduce risk of having one ISP seeing all connections

Monitor changes in peer behavior, statistics, etc.  
abnormal changes could be the sign of a partition

Longer-term countermeasures provide more guarantees but require protocol or infrastructure changes

Long-term

- Use end-to-end encryption or MAC
- prevent delay attacks (not partition attacks)

- Deploy secure routing protocols
- prevent partition attacks (not delay attacks)
